ACI 562-19, “Code Requirements for Assessment, Repair and Rehabilitation of Existing Concrete Structures,” was developed to provide design professionals a code for the assessment of the damage and deterioration, and the design of appropriate repair and rehabilitation strategies. The code provides minimum requirements for assessment, repair, and rehabilitation of existing structural concrete buildings, members, systems and where applicable, nonbuilding structures. ACI 562-19 was specifically developed to work with the International Existing Building Code (IEBC) or to be adopted as a stand-alone code.

Keywords: assessment; bond; corrosion; damage; durability; evaluation; existing structure; fiber-reinforced polymer (FRP); interface bond; licensed design professional; maintenance; rehabilitation; reliability; repair; strengthening.

Key changes from ACI 562-16 to ACI 562-19:
Summary of revisions, p. 94
Major revisions, p. 94
Minor revisions, p. 94
PREFACE

This code provides minimum requirements for assessment, repair, and rehabilitation of existing structural concrete buildings, members, systems and where applicable, nonbuilding structures. This code was developed by an ANSI-approved consensus process. This code can supplement the International Existing Building Code (IEBC), supplement the code governing existing structures of an authority having jurisdiction, or act as a stand-alone code in a locality that has not adopted an existing-building code. When this code is adopted as a stand-alone code, Appendix A should be used in place of Chapter 4.

The Code is specifically written for use by a licensed design professional. This code provides minimum requirements for assessment, design and construction, or implementation of repairs and rehabilitation, including quality assurance requirements, for structural concrete in service. This code has no legal status unless it is adopted by the authority having jurisdiction. Where the code has not been adopted, it serves as a standard to provide minimum requirements for assessment, and design and construction of repair and rehabilitation of existing structural concrete. ACI 318 provides minimum requirements for the materials, design, and detailing of structural concrete buildings and, where applicable, nonbuilding structures, and for new construction within existing structures where noted herein.

Key changes from ACI 562-16 to ACI 562-19 include:

(a) Text was added to simplify use of new materials that have the equivalent of an ICC-ES evaluation report in Chapter 1.
(b) The requirements for the basis of design report were simplified in Chapter 1.
(c) Requirements related to detailing of existing reinforcing steel in Chapter 4 have been clarified.
(d) The commentary in Chapter 8 was updated to include a listing of exposure categories that may affect durability.
CHAPTER 1—GENERAL REQUIREMENTS

1.1—General

1.1.1 ACI 562, “Code Requirements for Assessment, Repair, and Rehabilitation of Existing Concrete Structures,” is hereafter referred to as “this Code.”

1.1.2 Scope—This code shall apply to assessment, repair, and rehabilitation of existing concrete structures as:

1. A code supplementing the International Existing Building Code (IEBC)
2. As part of a locally adopted code governing existing buildings or structures
3. Or as a stand-alone code for existing concrete structures

1.1.3 The intent of this Code is to safeguard the public by providing minimum structural requirements for existing structural concrete members, systems, and buildings.

1.1.4 All references in this code to the licensed design professional shall be understood to mean persons who possess the knowledge, judgment, and skills to interpret and properly use this code and are licensed in the jurisdiction where this code is being used. The licensed design professional for the project is responsible for, and in charge of, the assessment or rehabilitation design, or both.

R1—GENERAL REQUIREMENTS

R1.1—General

R1.1.2 This code defines assessment, design, construction and durability requirements for repair and rehabilitation of existing concrete structures. Throughout this code, the term “structure” means an existing building, member, system, and, where applicable, nonbuilding structures where the construction is concrete or mixed construction with concrete and other materials.

Chapter 4 provides assessment, repair, and rehabilitation criteria if this code is used as a supplement to the International Existing Building Code (IEBC) for concrete members and systems.

Appendix A provides assessment, repair, and rehabilitation criteria when this Code is adopted, including Appendix A, as a stand-alone code for repair of existing concrete structures.

R1.1.3 The intent of this code is to address the safety of existing structures through assessment requirements that demonstrate an approximation of the structural reliability using demand-capacity ratio limits of Chapter 4 or Appendix A and, if necessary as determined by the assessment, increase the structural capacity by repair or rehabilitation.

Unless prohibited by the authority having jurisdiction, if an existing structure is shown to be potentially dangerous in accordance with 4.3 or A.3, the structure should be rehabilitated using 4.3 or A.3.

Using the demand-capacity ratio limits of 4.5.1 or A.5.1, repair of the existing structural concrete to its predeteriorated state is permitted based on material properties specified in the original construction (per Chapter 6), and substantiated engineering principles of the original design. Where requirements of the original building code are appreciably changed in the current building code, the licensed design professional may consider using 4.5.2 or A.5.2.

Beyond the restoration assessment requirements of 4.5.1 and 4.5.3 or A.5.1 and A.5.3, the structural reliability principles of 4.5.2 or A.5.2 are permitted. These alternative requirements provide acceptable safety if the current building code demand exceeds the original building code demand or if the regulations of the original building code provide an unacceptable level of structural reliability.
1.1.5 The requirements of this code are provided using strength design provisions for demands and capacities, unless otherwise noted.

1.2—Criteria for the assessment and design of repair and rehabilitation of existing concrete structures

1.2.1 The “existing building code” refers to the code adopted by a jurisdiction that regulates existing buildings or structures.

1.2.2 The “current building code” refers to the general building code adopted by a jurisdiction that regulates new building design and construction.

1.2.3 The “original building code” refers to the general building code applied by the authority having jurisdiction to the structure in question at the time the existing structure was permitted for construction.

R1.1.5 When this code permits the original building code regulations to be used and that code uses allowable stress design, the following should be considered: those provisions should be substituted for strength design as noted in 4.5.3 or A.5.3; the licensed design professional is not required to use, but should consider using strength design provisions of this code as a check in the assessment of existing structures originally designed with allowable stress methods.

R1.2—Criteria for the assessment and design of repair and rehabilitation of existing concrete structures

R1.2.1 The code governing existing buildings in the United States is commonly the IEBC developed by the International Code Council (ICC). The IEBC provides regulations for evaluations of damage and the limit for damage to be repaired using the original building code.

R1.2.2 The current building code establishes the design and construction regulations for new construction. Strength design regulations of the current building code include:

(a) Required strengths computed using combinations of factored loads (strength design demands)
(b) Design strengths (capacities) based on testing of materials, members, and systems
(c) Analytical methods used to calculate member and system capacity
(d) Strength reduction factors, which have been established to be consistent with reliability indices used with the strength design demands

The load factors and strength reduction factors in the current building code are obtained through rational design code calibration procedures to achieve the targeted reliability indices which produce historically acceptable structural safety for new structures. The targeted reliability indices are generally based on past structural behavior, engineering experiences, costs and consequences of loss, among other criteria. The resulting demand-capacity ratios for new structures provide the limits that are not to be exceeded if designing new construction, but these demand-capacity ratio limits need not to be the same as those for existing structures as noted in sections 4.5.2 and A.5.2.

The general building code in the United States is usually based on the International Building Code (IBC) published by the ICC. Prior to 2015, Chapter 34 of the IBC included provisions for existing structures. For the design and construction of new concrete structures, the IBC and most other older general building codes often reference ACI 318, Building Code Requirements for Structural Concrete and Commentary, with exceptions and additions.
1.2.4 Design-basis code criteria

1.2.4.1 The design-basis code criteria in this Code shall be used to assess and design repairs of existing members, systems, and structures.

having jurisdiction for the structure from the time of the original design through the time of the completion of construction. For buildings with major alterations or additions, the original building code should refer to the code in effect when the subject portion of the building was permitted, and different portions of a building may have different original building codes.

Reference to design requirements of the original building code should include: demands determined using either nominal loads, load factors, and load combinations of the original building code, or using allowable design loads and load combinations of the original building code; capacities determined using either strength design and reinforcement detailing provisions, and strength reduction factors of the original building code or using allowable stress design provisions of the original building code; and construction materials. Requirements for concrete design and construction include previous versions of ACI 318, concrete codes predating ACI 318, or concrete provisions within the original building code. A structural assessment using allowable stress design provisions of the original building code should be coupled with an evaluation using current standards or the strength design and reinforcement detailing provisions of this code to increase the understanding of structural behavior.

For a structure constructed prior to the adoption of a building code, the licensed design professional should research available standards and practices in effect at the time of construction. The Historic American Engineering Record, a program of the United States Park Service, has information on construction and preservation of historic structures (https://www.nps.gov/hdp/haer/).

R1.2.4 Design-basis code criteria

R1.2.4.1 The design-basis code criteria include requirements for assessment of the existing structure and for design when repairs are required based upon assessment results.

If a jurisdiction has adopted the IEBC and ACI 562 is used, then the design-basis code criteria are based on the IEBC with supplemental requirements of this code for potentially dangerous structural conditions, damage less than substantial structural damage, deterioration of concrete and reinforcement, faulty construction, serviceability issues, and durability of existing concrete.

For substantial structural damage, additions, alterations, and changes in occupancy, the IEBC establishes limits to which an assessment and design of repair and rehabilitation can occur in accordance with the original building code. Above these limits, an assessment and design of the repair and rehabilitation is in accordance with the current building code. Current and original building code provisions are supplemented by this code to address existing concrete members, systems, and structures.

Appendix A applies if a jurisdiction has not adopted the IEBC and has adopted this code. Appendix A of this code can provide design-basis code criteria for potentially dangerous...
1.2.4.2 Assessment and design-basis criteria and the
requirements for applying these criteria are provided in
Chapter 4 and Appendix A. Chapter 4 applies if a jurisdic-
tion has adopted the International Existing Building Code
(IEBC) as the existing building code. Appendix A applies if
a jurisdiction has not adopted the IEBC or if a jurisdiction
has adopted this code.

1.2.4.3 Assessment criteria shall be used to classify the
work and to establish the design-basis criteria.

1.2.4.3.1 It shall be permitted to use the current building
code as the assessment criteria for all existing structures.

1.2.4.4 Design-basis criteria shall be used to establish the
applicable building code for repair and rehabilitation design.

1.2.4.5 The current building code shall be the design-basis
code for new members and for connection of new members
to existing structures.

1.2.4.5.1 The exceptions to 1.2.4.5 occur for the following:
1) when seismic retrofits are designed using the alternate
design criteria of ASCE 41, or 2) when new members are
added within the work area using the original building code
as the design-basis code criteria for the repair.

1.3—Applicability of this code

1.3.1 This code provides minimum requirements when
performing an assessment, repair or rehabilitation design
and remedial construction of the structural components
of existing concrete structures, including buildings and
nonbuilding structures.

1.3.1.1 Regulations of the current building code need not
be exceeded when assessing, designing repair and rehabili-
tation work, or installing remedial work of existing structures.

1.3—Applicability of this code

R1.2.4.2 Classifying the work category using criteria and
requirements of Chapter 4 or Appendix A defines the design-
basis criteria, which is used to design the repair or rehabilita-
tion work.

R1.2.4.3.1 Use of the current building code for assess-
ment criteria may result in a conservative assessment of an
older structure. The design professional should review use of
the current building code with the Owner at the start of the
project (refer to R1.3.1).

R1.2.4.5.1 The performance-based criteria in ASCE 41
may result in new member design that will not satisfy current
code requirements for strength, stiffness, or detailing. New
concrete members and reinforcement may be designed by
the original building code if integrated with the work area
repair construction of the existing structure when the repair
design-basis criteria for the existing structure is the original
building code. The detailing of these new members and the
connection of these members to the existing concrete should
be according to the current building code.

R1.3—Applicability of this code

R1.3.1 In typical U.S. practice, Owners are required to
maintain existing structures to prevent unsafe conditions
from occurring, or repair an existing structure when unsafe
conditions are present. The minimum level of repair for an
existing building will typically address these unsafe and
potentially unsafe conditions.

The licensed design professional is permitted to perform
assessment, design, and quality assurance activities that
exceed the minimum requirements of this Code. Consider-
ations beyond the minimum requirements of this Code, such
as those for progressive collapse resistance, redundancy,
or integrity provisions are permitted. Exceeding the code
minimum requirements is not a violation of this Code.
### CODE

1.3.2 This Code is applicable to existing nonbuilding concrete structures.

1.3.3 Foundations

1.3.3.1 This code shall apply to the assessment and repair or rehabilitation of existing structural concrete foundation members.

R1.3.3 Foundations

1.3.4 Soil-supported slabs

1.3.4.1 This code shall apply to the assessment and repair or rehabilitation of soil-supported structural slabs that transmit vertical loads or lateral forces from the structure to the soil.

1.3.5 Composite members

1.3.5.1 This code shall apply to the assessment and repair or rehabilitation of the concrete portions of composite members.

1.3.6 Precast and prestressed concrete

1.3.6.1 The code shall apply to the assessment and repair or rehabilitation of structural precast and prestressed concrete members, systems, and connections. The code shall apply to cladding transmitting vertical loads to supporting members or lateral loads to diaphragms or bracing members.

1.3.7 Nonstructural concrete

R1.3.7 Nonstructural concrete

The Owner and the design professional should agree on the intent of the repair and rehabilitation program and desired outcome at the onset of the project. The desired repair outcome may include consideration of the design service life of the repairs, structural reliability, serviceability considerations, and other factors. Due to the uncertain remaining service life of existing structures and the technical requirements of repair construction, quality assurance and construction observations in excess of that required by general building code is commonly required. The desired outcome of the repair and rehabilitation program, quality assurance, and construction observation requirements should be documented in the basis of design (Section 1.5.3).

R1.3.2 Nonbuilding concrete structures can include, but are not limited to arches, tanks, reservoirs, bins and silos, blast- and impact-resistant structures, and chimneys.

R1.3.3 Foundations

R1.3.3.1 Foundation members and systems should include those constructed using plain or reinforced concrete including but not limited to spread footings, mat foundations, concrete piles, drilled piers, grade beams, pile and pier caps, and caissons embedded in the ground. The design and installation of new pilings fully embedded in the ground are regulated by the current building code. For repair of existing foundation members and systems, the provisions of this code apply if not in conflict with the code governing existing building. For the portions of concrete piling in air or water, or in soil not capable of providing adequate lateral restraint throughout the piling to prevent buckling, the provisions of this code govern.
1.3.7.1 This code is not intended for repair of nonstructural concrete or for aesthetic improvements, except if failure of such repairs would result in an potentially dangerous condition.

1.3.8 Seismic resistance

1.3.8.1 Evaluation of seismic resistance and design of retrofit shall be in accordance with the code governing existing buildings if one has been adopted or this code if a code governing existing buildings has not been adopted. If using this code for evaluation of seismic resistance and retrofit design, ASCE/SEI 41 shall apply.

1.3.8.2 If retrofit for seismic resistance is not required by the code governing existing buildings or by this code, voluntary seismic retrofit shall be permitted.

1.3.8.2.1 When this code is used without the IEBC, the licensed design professional shall use the current building code supplemented by ASCE/SEI 41 and ASCE/SEI 7 to design voluntary seismic retrofits.

1.4—Administration

1.4.1 Whenever this code is in conflict with the regulations of the authority having jurisdiction or code governing
CODE

existing buildings, the authority having jurisdiction or code governing existing buildings shall govern.

1.4.2 Whenever this code is in conflict with requirements in other referenced standards, this code shall govern.

1.4.3 Approval of special systems of design or construction—Systems that are approved by the authority having jurisdiction through alternative means and methods clauses in the building design-basis code shall be permitted.

1.4.4 Materials that are evaluated in a process equivalent to the requirements of the IBC shall be used in accordance with the requirements of the written evaluation report for the material. Material use shall satisfy requirements of this code.

1.5—Responsibilities of the licensed design professional

1.5.1 The licensed design professional for the project is responsible for 1) assessing; 2) designing, detailing, and specifying the work proposed and material requirements; 3) consideration of load paths for the work proposed; and 4) preparing construction documents of the work proposed and specifying a quality assurance program. Construction documents shall indicate the location, nature, and extent of the work proposed.

1.5.2 Potentially dangerous structural conditions—The licensed design professional for the project shall report observations of exposed structural defects in the existing construction within the work area representing visible potentially dangerous structural conditions requiring evaluation and possible mitigation to the Owner.

1.5.2.1 When required by the authority having jurisdiction, visible potentially dangerous conditions shall be reported by the licensed design professional to the authority having jurisdiction.

COMMENTARY

R1.4.3 New methods of design, new materials, and new uses of materials for repair and rehabilitation usually undergo a period of development before being specifically covered in a code. Hence, good systems or components might be excluded from use by implication if means are not available to obtain acceptance. For systems considered under this section, specific tests, load factors, strength reduction factors, deflection limits, and other pertinent requirements should be set by the authority having jurisdiction and should be consistent with the intent of this code. Provisions of this section do not apply to model analysis used to supplement calculations or to strength evaluation of existing structures.

R1.4.4 The IBC (Section 1703 in IBC 2018) includes provisions for approval of alternate materials in new construction. The approval process requires the evaluation to be completed by an approved agency, and the material properties and use requirements be summarized in a written evaluation report. The same process may be used for materials in repair applications, provided the materials satisfy the provisions of this code. This process is intended to allow for use of new materials and new classes of materials that do not have approved design or material standards.

R1.5—Responsibilities of the licensed design professional

R1.5.1 During the assessment part of the investigation, the licensed design professional should request that the Owner provide all available information regarding the condition of the building, construction documents, previous engineering reports, disclose the presence of any known hazardous materials in the work area, and any other pertinent information to the parties involved in the work. This information may require that remedial measures be taken before or during the construction process and should be considered in the scope of work.

R1.5.2 During investigation or repair construction, potentially dangerous structural conditions in the work area may be revealed. To protect the public safety, an observed potentially dangerous structural condition should be reported to the contractor and Owner to initiate mitigation of the condition. Mitigation may include temporary shoring or construction as part of the remedial work.
1.5.3 The licensed design professional for the project shall document the basis of design. The basis of design shall address work categories and repair construction within the work area for each structural element and include:

(a) A description of the building
(b) Modifications such as additions, alterations, or changes in occupancy
(c) Elements of existing structure to be shored
(d) Quality assurance and quality control (QA/QC) requirements
(e) Conditions and details of the proposed rehabilitation work
(f) Assessment criteria and findings
(g) Repair material requirements
(h) Known history of repairs and rehabilitation

R1.5.3 The basis of design provides a summary of the assessment of the existing structure, and a summary of the construction documents from original construction or prior rehabilitation used in developing the basis of design. The basis of design can be documented in a written report or included in construction documents. Information on some structures may be unavailable or unnecessary if strengthening is not required and should be so documented in the basis of design. The licensed design professional should review requirements of the authority having jurisdiction to determine the information to include in the basis of design documentation and filing requirements for the basis of design.

Additional materials that may be documented in the basis of design include:

(a) Detailed building description, including age of construction, structural systems, identified original building code, and past and current uses
(b) Documentation of potentially dangerous structural conditions in the work area of the structure determined in the assessment
(c) Documentation of substantial structural damage in the work area
(d) Members and systems of the work area requiring increase in capacity beyond the demand of the original building code
(e) Conditions and details of the proposed rehabilitation work
(f) Assessment criteria and findings
(g) Design-basis code criteria and basis of rehabilitation design
(h) Shoring requirements such as loads and spacing of shoring members
(i) Quality assurance and quality control (QA/QC) requirements
(j) Types and frequency of future inspection
(k) Types and frequency of future maintenance
(l) Recommendations to address serviceability conditions as discussed in Section 6.6

A maintenance protocol that addresses project-specific conditions provides the most effective method to ensure durability and should be established as part of the repair or rehabilitation design that includes inspections and period of time between inspections, after completion of the repair installation. Maintenance and frequent preventative approaches that occur early in the service life of the structure generally result in improved service life with less interruption and a lower life-cycle cost (Tuutti 1980; ACI 365.1R). Recommendations should be provided to the Owner on inspection and maintenance to be undertaken during the remaining design service life of the repair material or the repaired part of the structure.

A maintenance protocol should be provided in the basis of design, or in as-built or close-out documents. Maintenance of the repair can be incorporated in the instruction manuals from the licensed design professional, contractor, or product manufacturers. Documents and records of observations,
1.6—Construction documents

1.6.1 The construction documents for rehabilitation work proposed shall provide sufficient detail and clarity to convey the location, nature and extent of the work, and the necessary information to perform the work in conformance with the requirements of this code and the local authority having jurisdiction. Specifications shall require that materials used for repair and rehabilitation construction satisfy this code and governing regulatory requirements at the time the work is implemented.

1.6.2 Calculations pertinent to design shall be submitted with the construction documents if required by the authority having jurisdiction. Scale-model testing and analysis shall be permitted to supplement calculations.

1.6.3 To the extent required by the contract between the licensed design professional and Owner, the licensed design professional shall provide the Owner with copies of the basis of design report, assessment reports, project documents, field reports, locations of completed repairs, and other project documents.

1.7—Preliminary assessment

1.7.1 Preliminary assessment of an existing structure shall include investigation and review of the structure, construction documents, reports, local jurisdictional codes, and other available documents of the existing structure. Existing in-place conditions shall be visually or otherwise investigated to verify existing geometry and structural conditions.

R1.6—Construction documents

R1.6.1 As necessary, the construction documents should indicate:

(a) Name and date of issue of the building code and supplements to which the assessment, repairs, or rehabilitation conforms
(b) Design-basis code criteria used for conditions addressed by the documents
(c) Design assumptions and construction requirements including specified properties of existing and remedial materials used for the project and the strength requirements at stated ages or stages of the construction
(d) Details, locations and notes indicating the size, configuration, reinforcement, anchors, repair materials, preparation requirements, and other pertinent information to implement the repairs, strengthening, or rehabilitation of the structure
(e) Magnitude and location of prestressing forces
(f) Anchorage details for prestressing reinforcement
(g) Development length of prestressing forces
(h) Type and location of mechanical or welded splices of reinforcement
(i) Shoring or bracing criteria necessary before, during, and at completion of the assessment, repair, or rehabilitation projects
(j) Quality assurance program including specific inspections and testing requirements

ACI 563 is a reference specification that is written to be consistent with the requirements of this Code.

R1.6.2 Analyses and designs should include calculations, evaluation and design assumptions. If computer-based analyses and designs, such as finite element methods are used, they should include input, and computer-generated output.

R1.6.3 Documentation of the project and repairs that have been carried out, including structural observations, inspection reports by others, test results, and recommendations on inspection and maintenance to be undertaken during the remaining design service life of the repaired part of the concrete structure, should be provided to the Owner. The extent and type of quality assurance records should include those required in the construction documents. It is good practice for the Owner to keep documentation of repairs, inspections, testing, monitoring, and investigations for future reference.

R1.7—Preliminary assessment

R1.7.1 The goal of the preliminary assessment is to examine available information about the structure within the work area, and to make an initial determination of its adequacy to withstand in-place environmental conditions and design loads. The results of the preliminary assessment should be used to make decisions regarding the current
in-place condition, need for additional information, work items necessary as part of the assessment, possible rehabilitation design and construction work to consider, and if there is a need for temporary shoring for safety of the existing structure. The preliminary assessment results should be updated as additional data regarding the examined structure become available.

The licensed design professional may determine that 4.6 or A.6 applies in a preliminary assessment based on engineering judgment and without analysis if all of the following are confirmed:

(a) Historical performance of the structure and visual observation of the structural condition of members and systems indicate acceptable behavior precluding assessment by 4.3 or A.3

(b) Review of construction documents and observation of current structural conditions indicate damage or deterioration of the structure below the level requiring assessment by 4.4 and 4.5 or A.4 and A.5

(c) Modifications for additions, alterations, and changes in occupancy are not planned.

Repairs are permitted that address durability and serviceability of 4.6 or A.6 without analyzing members and systems and checking the demand-capacity ratio limits of 4.3 through 4.5 or A.3 through A.5 if the structure is determined to be structurally acceptable. Structural performance should be considered acceptable if past and present performance has been satisfactory and observations do not indicate structural distress beyond levels expected.

The extent of damage or deterioration should be limited and the licensed design professional should not have a concern about the capacity of the structure if repairs are completed using the provisions of 4.6 with verifying the demand to capacity limits of 4.4 and 4.5 or A.4 and A.5.

R1.7.2 Potentially dangerous structural conditions may require the Owner to install shoring, limit access, or take other measures to mitigate these conditions.

R1.7.3 The assumed preliminary assessment criteria should be substantiated or modified in accordance with the assessment details of Chapter 6.

R1.7.4 When required as a part of the preliminary assessment, strength calculations should be based on in-place conditions and should include an assessment of the loss of strength due to deterioration mechanisms. Guidelines for assessing in-place conditions include ACI 201.2R, ACI 214.4R, ACI 228.1R, ACI 228.2R, ACI 364.1R, ACI 437.1R, FEMA P-58, FEMA P-154, FEMA 306, FEMA 307, ASCE/SEI 11, ASCE/SEI 41, ATC-20, ATC-45, and ATC-78 as well as The Concrete Society Technical Report 68 (2008). When material test results are initially unavailable, historical properties based on typical values used at the time of
construction can be used in preliminary evaluation. If available, material properties from construction documents can also be used in a preliminary evaluation.

The assessment of existing structures should initially focus on critical gravity-load-resisting members such as columns, walls, and members that are expected to have limited ductility, followed by an assessment of the lateral-load-resisting system.

Assessing fire damage and other deterioration mechanisms that result in a change in material properties (such as compressive strength or modulus of elasticity) should include an evaluation of the effect of the damage on the material properties and the impact of the damage on the performance of the existing structure. Examples of deterioration mechanisms that result in possible changes in material properties include corrosion of steel reinforcement, thermal damage, concrete reactions such as alkali-aggregate, and freezing and thawing.

Conditions to be documented include cracking, spalls, member deflection, cross-section dimensions different than specified on the original construction drawings, and construction deviating from tolerances permitted under the original design criteria.

CHAPTER 2—NOTATION AND DEFINITIONS

2.1—Notation

This chapter defines notation and terminology used in this code.

c = depth of neutral axis, in.

D = dead load acting on the structure

d т = distance from extreme compression fiber to centroid of extreme tension reinforcement, in.

f_c = average core strength modified to account for the diameter and moisture condition of the core, psi

f_c’ = specified concrete compressive strength, psi

f_{eq} = equivalent specified concrete strength used for evaluation, psi

f_y = specified yield strength of steel reinforcement, psi

f_y’ = average yield strength value for steel reinforcement, psi

f_{eq} = equivalent yield strength of steel reinforcement used for evaluation, psi

k_c = coefficient of variation modification factor for concrete testing sample sizes

k_s = coefficient of variation modification factor for steel testing sample sizes

L = live load acting on the structure

ℓ_t = span of member under load test and taken as the smaller of: (a) distance between centers of supports; and (b) clear distance between supports plus thickness h of member; for a cantilever, it shall be taken as twice the distance from face of support to cantilever end, in.

n = number of sample tests

R_a = service load capacity of structural member, system, or connection including effects of damage, deterioration of concrete and reinforcement, and faulty construction determined using allowable stresses according to the original building code.

R_{en} = current in-place nominal capacity of structural member, system, or connection including the effects of damage, deterioration of concrete and reinforcement, and faulty construction

R_{ex} = nominal resistance of the structure during an extraordinary (that is, low-probability) event computed using the probable material properties

R_a = nominal capacity of structural member, system, or connection excluding the effects of damage, deterioration of concrete and reinforcement, and faulty construction

S = snow load acting on the structure

T_g = glass transition temperature, °F

U = demand using nominal loads and factored load combinations for strength design provisions (LRFD)

U_c = demand using nominal loads of the current building code and factored load combinations of ASCE/SEI 7 for strength design provisions (LRFD)
CODE

\(U_o\) = demand using nominal loads and factored load combinations of the original building code for strength design provisions (LRFD)

\(U_o^*\) = demand using nominal loads of the original building code and factored load combinations of ASCE/SEI 7 for strength design provisions (LRFD)

\(U_r\) = demand using service loads of the original building code and load combinations of the original building code

\(V\) = coefficient of variation (a dimensionless quantity equal to the sample standard deviation divided by the mean) determined from testing of concrete or steel samples from structures

\(v_{ni}\) = nominal interface shear stress capacity

\(v_u\) = resultant interface stress demand from the transfer of tension and shear

\(e_t\) = net tensile strain in the extreme tension reinforcement at nominal strength

\(e_y\) = yield strain of steel reinforcement

\(\phi\) = strength reduction factor

\(\phi_{ex}\) = strength reduction factor used to check strength of the structure without external reinforcement after an extraordinary event

\(\phi_o\) = strength reduction factor from the original building code used in the design of an existing structure

COMMENTARY

2.2—Definitions

ACI provides a comprehensive list of definitions through an online resource, “ACI Concrete Terminology.” Definitions provided here complement that resource.

- assessment—refer to structural assessment.
- assessment criteria—codes, standards, loads, demands, capacities, strength reduction factors, materials, material properties, connections, details, and protections used in the evaluation.
- authority having jurisdiction—person or entity that has legal control over the applicable building code and permitting procedures for a structure.
- bond—(1) adhesion of applied materials to reinforcement or other surfaces against which they are placed, including friction due to shrinkage and longitudinal shear in the concrete and repair materials engaged by the bar deformations; (2) adhesion or cohesion between layers of a repair area or between a repair material and a substrate produced by adhesive or cohesive properties of the repair material or other supplemental materials throughout the service life of the repair.
- bond-critical application—strengthening or repair system that relies on load transfer from the substrate to the system material achieved through shear and tension transfer at the interface, where bond rather than mechanical attachment is used as the primary load transfer mechanism.
- capacity—the strength, stiffness, ductility, energy dissipation and durability, of a material, member or system as determined by analysis or testing.

R2.2—Definitions

Additional repair-related definitions are provided by “ICRI Concrete Repair Terminology”.

An example of an authority having jurisdiction is the local building official.

This definition has been expanded from “ACI Concrete Terminology” for this code.
compatible—the ability of two or more materials to be placed in contact or in sufficiently close proximity to interact with no significant detrimental results with respect to the intended service life.

connector steel—steel elements, such as reinforcing bars, shapes, or plates, embedded in concrete or connected to embedded elements to transfer load, restrain movement, or provide stability.

contact-critical application—strengthening or repair system that relies on load transfer from the substrate to the system material achieved through bearing perpendicular to the interface.

construction documents—written and graphic documents and specifications prepared or assembled that describe the location, design, materials, and physical characteristics of the elements of a project necessary for obtaining a building permit and for construction of the project.

damage—a decrease in the capacity of an existing member or structure resulting from events, such as loads and displacements, or as a result of deterioration of the structure.

dangerous—any building, structure, or portion thereof that meets any of the conditions described below shall be deemed dangerous:
1. The building or structure has collapsed, has partially collapsed, has moved off its foundation, or lacks the necessary support of the ground.
2. There exists a significant risk of collapse, detachment or dislodgement of any portion, member, appurtenance, or ornamentation of the concrete building or structure under service loads.

demand—the force, deformation, energy input, and chemical or physical attack imposed on a material, member, or system which is to be resisted.

design-basis code—legally adopted code requirements under which the assessments, repairs, and rehabilitations are designed and constructed.

design-basis criteria—codes, standards, loads, displacement limits, material properties, connections, details, and protections used in the design of mandated or voluntary work.

design service life (of a building, component, or material)—the period of time after installation or repair during which the performance satisfies the specified requirements if routinely maintained but without being subjected to an overload or extreme event.

deterioration—(1) physical manifestation of failure of a material (for example, cracking, delamination, flaking, pitting, scaling, spalling, and staining) caused by environmental or internal autogenous influences on rock and hardened concrete as well as other materials; (2) decomposition of material during either testing or exposure to service. (See also disintegration and weathering in ACI CT.)

durability—ability of a material or structure to resist weathering action, chemical attack, abrasion, and other conditions of service and maintain serviceability over a specified time or service life.

An example of a contact-critical application is the addition of a confinement jacket around a column.

This definition has been adopted from the IEBC. Potentially dangerous conditions of an existing concrete member, system, or structure may include those defined as dangerous from the IEBC. Circumstances may render some conditions defined as dangerous to be potentially dangerous within a limited period of time or may be concluded to be less of an imminent hazard.
**equivapent cover**—a system to supplement insufficient concrete cover to improve durability or fire protection to that equivalent to the minimum cover specified in the design-basis code.

**evaluation**—refer to structural evaluation.

**existing structure**—structure for which a legal certificate of occupancy has been issued. For structures that are not covered by a certificate of occupancy, existing structures are those that are complete and permitted for use or otherwise legally defined as an existing structure or building.

**factored load**—product of the nominal load and load factor.

**faulty construction**—deficient construction resulting from errors or omissions in design or improper construction causing displacement of supporting portions of the structure or resulting in deficient materials, geometry, size or location of concrete members, reinforcement or connections that result in a decrease in the capacity of an existing structure or an adverse impact on the long-term durability or serviceability of the structure.

**in-place condition**—current condition of an existing structure, system, member, connection including component sizes and geometry, material properties, faulty construction, deterioration, and damage from an event.

**interface reinforcement**—(1) existing or supplemental reinforcement that is properly anchored on both sides of an interface; (2) post-installed reinforcement such as adhesive anchors or mechanical anchors, or other mechanical connections providing a method of force transfer across an interface.

**interface shear stress**—shear stress resulting from transfer of forces at bonded interfaces between repair material and existing substrate used to achieve composite behavior.

**licensed design professional**—(1) an engineer or architect who is licensed to practice structural design as defined by the statutory requirements of the professional licensing laws of a state or jurisdiction; (2) the engineer or architect, licensed as described, who is responsible for the structural design of a particular project (also historically engineer of record).

**nominal load**—magnitude of load specified by the design-basis code before application of any load factor.

**nonstructural concrete**—any element or portion thereof made of plain or reinforced concrete that is not required to transfer gravity load, lateral load, or both, along a load path of a structural system to the ground.

**Owner**—corporation, association, partnership, individual, or public body or authority with whom the contractor enters into an agreement and for whom the work is provided. The Owner is the party in legal possession of the structure.

**potentially dangerous**—(1) structural state of existing concrete within a work area for an individual structural member, structural system, or structure meets the definition of dangerous or unsafe, is unstable, has potential of collapse of overhead components or pieces (falling hazards), has

The definition is different from the IEBC definition of an existing building. The IEBC definition is “A building erected prior to the date of adoption of the appropriate code, or one for which a legal building permit has been issued.” When using this code with the IEBC, use of the IEBC definition is appropriate.

This definition is adopted from “ACI Concrete Terminology.”

Potentially dangerous conditions of an existing concrete member, system, or structure include conditions that may be defined as dangerous or unsafe in the IEBC. These conditions may be overtly hazardous, dangerous, or unsafe depending
been determined to have demand/capacity ratio exceeding the limit of Section 4.3.2.2 or has potentially hazardous resistance for seismic events. (2) A limit state of unacceptably low margin of safety against collapse without supplemental resistance.

**rehabilitation**—repairing or modifying an existing structure to a desired useful condition.

**repair**—the reconstruction or renewal of concrete parts of an existing structure for the purpose of its maintenance or to correct deterioration, damage, or faulty construction of members or systems of a structure.

**repair reinforcement**—reinforcement used to provide additional strength, ductility, confinement, or any combination of the three, to the repaired member.

**repair, structural**—restoring a damaged or deteriorated structure or increasing the capacity of a structure.

**repair system**—the combination of existing and new components, which may include existing reinforcement, repair materials, supplementary reinforcement and supplemental structural members.

**retrofit**—modification of an existing member, system, or structure to increase its strength, ductility, or both as a means of improving the seismic performance of the structure.

**serviceability**—structural performance under service conditions.

**shoring**—props or posts of timber, steel, or other material used for the temporary support of excavations, formwork, members during repairs, or potentially dangerous structures; the process of erecting shores.

This definition is adapted from ACI Concrete Terminology—“the process of repairing or modifying a structure to a desired useful condition.” The definition is specific for concrete rehabilitation and is inclusive of the IEBC definition—“Any work, as described by the categories of work defined herein, undertaken in an existing building.” Herein, concrete rehabilitations include: repair to restore original capacity; strengthening to increase the capacity to the current building code requirements; seismic retrofits per ASCE/SEI 41; and modifications addressing additions, alterations, and change of occupancy.

The definition of repair from ACI Concrete Terminology is “to replace or correct deteriorated, damaged, or faulty materials, components, or elements of a structure.” The definition of repair from IEBC is “The reconstruction or renewal of any part of an existing building for the purpose of its maintenance or to correct damage.” The definition herein is adapted from the IEBC and is specific for repair of materials, components, or elements of existing concrete structures where structural repair or durability is addressed. Faulty materials, components, or elements of a structure are interpreted to be faulty construction resulting from errors or omissions in design or construction.

This definition is adapted from ACI Concrete Terminology—“increasing the load-carrying capacity of a structural component beyond its current capacity or restoring a damaged structural component to its original design capacity.” Herein, the definition addresses increasing the capacity to include enhancements such as ductility of existing concrete members. Repairs to nonstructural members, whose failure would cause or result in potentially dangerous structural conditions are considered structural repairs.

Typically used to refer to seismic modifications to increase resistance in an existing structure per ASCE/SEI 41. The definition is adapted from ASCE/SEI 41—“Improving the seismic performance of structural or nonstructural components of a building.”
**CODE**

**specialty engineer**—a licensed design professional retained by a contractor to design a delegated portion of the project.

**stability, global**—stability of the overall existing structure with respect to vertical support, uplift, overturning, sway instability, or sliding failure.

**stability, local**—the stability of an individual member or part of an individual member.

**strengthening**—process of increasing the capacity of an existing structure or a portion thereof.

**structural analysis**—process of using engineering mechanics to determine internal demands on, and capacities of a structure, member, or system.

**structural assessment**—the process of investigating by systematically collecting information regarding the performance of an existing structure; and evaluating the collected information to make informed decisions regarding the need for repair or rehabilitation; and detailing of findings as conclusions and reporting recommendations for the examined structural concrete work area (member, system, or structure).

**COMMENTARY**

The term “specialty engineer” is used in Chapter 9. In this code, the specialty engineer will typically be a licensed design professional that is retained by the contractor to design specific types of components such as precast concrete or shoring members.

This definition with specific details for existing concrete is adapted from ASCE/SEI 11—“Systematic collection and analysis of data, evaluation, and recommendations regarding the portions of an existing structure which would be affected by its proposed use.”

A structural assessment is the process of acquiring knowledge of the existing structure used for the purpose of judging the future performance. The results of the investigation and evaluation are used to make decisions on the appropriate course of action regarding the future use of the structure and the suitability of the structure to continue in service. Herein, assessments should be limited to the work area and may include:

(a) Investigation of the in-place condition of the existing structure by:
   i. Collection and review of field data for the structure, such as geometry, material strengths, conditions, symptoms of distress, extent of damage, measurement of displacements, environmental factors and reinforcement sizes, and placement
   ii. Collection of background data, such as construction plans, construction records, original, current, and code governing existing buildings, and historical events

(b) Evaluation of an existing structure, member or system of the work area (refer to commentary for structural evaluation)

(c) Findings and conclusions of the investigation and evaluation include:
   i. Define the existing structure, member, or system rehabilitation category using the assessment criteria of this code
   ii. Identify the work area, scope of work and likely cause or mechanism of damage, distress and deterioration
   iii. Identify faulty construction limitations
   iv. Evaluate test results to determine cause of failure and predict future performance.

(d) Determine repair and rehabilitation concepts, strategies, alternatives and recommendations
   i. Develop cost-impact or economic study as necessary to appraise remedial work and maintenance
   ii. Describe repair and rehabilitation work recommendations
**structural concrete**—plain or reinforced concrete in a member that is part of a structural system required to transfer gravity loads, lateral loads, or both, along a load path to the ground.

**structural evaluation**—the process of determining and judging the structural adequacy of a structure, member, or system for its current intended use or performance objective.

This definition is adapted from ASCE/SEI 11 — “The process of determining the structural adequacy of the structure or component for its intended use, performance, or both. Evaluation by its nature implies the use of personal and subjective judgment by those functioning in the capacity of experts.” An evaluation should determine, to the best of the license design professional’s knowledge, the level of quality (structural adequacy, serviceability, or durability) of an existing structure based upon a measured criteria and the judgment of the licensed design professional. An evaluation may require professional judgment to gage structural adequacy. Structural analyses may be required to determine possible ranges of existing structure capacities and variations in demands. The goal of the evaluation process is to appraise the in-place condition to determine adequacy for current or proposed future use. Structural evaluation requires determining capacity and demand, which may vary widely depending on the acquired information, tests, models, and analyses; determining the demand-capacity ratios; and judging structural reliability limits, which may be open to interpretation based on project requirements, structural experience, knowledge, and past performance.

Evaluation activities may include:

(a) Tests to confirm reinforcement location, strength of material properties or structural capacity of existing members or systems or for presence of contaminants.

(b) Analysis of test results to establish reinforcement, statistical equivalent material properties, limits of faulty construction, and structural capacity

(c) Screening of observations and tests for mechanisms and causes of damage, distress, and deterioration

(d) Establishing the assessment criteria

(e) Calculating demand loadings, serviceability limits, lateral displacements, and durability requirements

(f) Analysis of the structure to determine the capacity of the structure to withstand current or future load demands and comply with serviceability limits

   i. Determination of demand-capacity ratios to appraise structural adequacy, ascertain classifications, and judge the need for repair and rehabilitation

   ii. determination of maintenance requirements necessary for the service life of the structure
substantial structural damage—except when using Appendix A, substantial structural damage shall be as defined in the IEBC.

When using this code as a stand-alone code, substantial structural damage shall be as defined in A.4.

temporary bracing—non-permanent supplemental members added to an existing structure to prevent local or global instability during assessment and repair construction.

undercutting—concrete removal around the reinforcement circumference to allow for existing reinforcement to be encapsulated in repair material.

The definition of substantial structural damage is from the IEBC. The definition has been modified, as noted in A.4, when using this code as a stand-alone code.
Both current and withdrawn standards are referenced. Standards that are referenced in the design-basis code are applicable for the assessment of existing structures. These standards may have been withdrawn by the developing organization; however, they provide information on the materials used at the time of original construction. Refer to 4.3.3 and Chapter 6.

IEBC—International Existing Building Code
CODE

CHAPTER 4—CRITERIA WHEN USING THIS CODE WITH THE INTERNATIONAL EXISTING BUILDING CODE (IEBC)

4.1—General

4.1.1 This chapter applies if a jurisdiction has adopted the International Existing Building Code (IEBC) as the existing building code. When this chapter is used, Appendix A does not apply.

4.1.2 The design-basis code criteria of the project shall be determined based upon the results of the preliminary assessment (1.7) and the detailed assessment (Chapter 6), if performed, using the requirements set forth in this chapter.

4.1.3 It shall be permitted to use the current building code in place of the original building code as the design-basis criteria for all damage states, deterioration, faulty design, or faulty construction.

4.1.4 It shall be permitted to use this code in conjunction with the IEBC to determine the work category as shown in Table 4.1.4.

COMMENTARY

R4—CRITERIA WHEN USING THIS CODE WITH THE INTERNATIONAL EXISTING BUILDING CODE (IEBC)

R4.1—General

R4.1.1 Appendix A is used when this code is used for existing concrete structures as a stand-alone code without the IEBC and may be used to supplement provisions of Chapter 34 in 2012 and previous versions of the IBC.

R4.1.2 Structures constructed under previously adopted codes or before the adoption of a building code may not satisfy all current building code requirements. This Code and the IEBC contain specific requirements that determine if existing structures should be repaired, rehabilitated, or retrofitted to satisfy the requirements of the design-basis code. Local ordinances may also require that a structure be rehabilitated to satisfy the current codes. These requirements should be reviewed at the start of a project.

In the absence of mandatory local ordinances, the licensed design professional should determine if a seismic evaluation is necessary for potentially hazardous conditions using Section 4.3.3. Section 4.3.3 provides minimum assessment criteria for potentially hazardous seismic conditions. Provisions of ASCE/SEI 41 may be applicable to nonbuilding structures being assessed.

R4.1.3 Refer to Section R1.2.4.3.1 for additional commentary on use of current building code as the design-basis criteria.

R4.1.4 Unless the local jurisdiction provides more restrictive requirements, this chapter with the IEBC should be used to determine the assessment and design-basis criteria based on the work category of Table 4.1.4.
**CODE**

**R4.1.5** New member or reinforcement that is part of the work area repairs and built jointly with the existing structure should be designed using the same criteria as other repairs to the structure. However, the detailing of new members and detailing of added reinforcement, including connections to the existing structure, should comply with the current building code.

**R4.1.6** The licensed design professional should review the development of existing reinforcing steel, when cracking damage is evident near the ends of reinforcement, to determine if the cracking is indicative of potential development failure beyond the restrictions of this section. Research has shown that development length equations from previous versions of ACI 318 may be unconservative for top cast plain reinforcing steel bars (Feldman and Cairns 2017). Significant changes have occurred in the building code requirements increasing the development of reinforcing steel.

When the basis of design is the current building code, the licensed design professional should consider the following:

(a) Assessing demand/capacity ratios for the existing reinforcing steel with current development length provisions
(b) Confinement details of the reinforcement when assessing seismic resistance

The licensed design professional should determine if structural behavior indicates adequate performance. ACI
4.2—Compliance method

4.2.1 The compliance method selected and the design-basis criteria shall be used consistently for all assessment and rehabilitation design, excluding other options.

4.3—Potentially dangerous structural conditions

4.3.1 A structural assessment shall be performed in the work area to determine if potentially dangerous structural conditions are present when there is a reason for the licensed design professional to question the capacity of the structure or when potentially dangerous structural conditions are observed as a part of the preliminary assessment.

4.3.1.1 Potentially dangerous structural conditions shall be reported in accordance with 1.5.2.

4.3.2 For gravity, fluid, soil, and wind loads, potentially dangerous structural conditions exist in members or structures where the demand/capacity ratio is greater than 1.5, as shown in Eq. (4.3.2).

\[ \frac{U_i}{\phi R_m} > 1.5 \]  

(4.3.2)

In Eq. (4.3.2), \( U_i \) is the strength design demand determined by using the nominal loads identified in the current building code and the factored load combinations of ASCE/SEI 7, excluding seismic forces; and \( \phi R_m \) is the capacity adjusted by the strength reduction factor \( \phi \) in Section 5.3 or 5.4 of this code.

4.3.2.1 If the demand/capacity ratio exceeds 1.5 for the work area, the design-basis criteria shall be the current building code.

4.3.2.2 For structures with no potentially dangerous conditions, Sections 4.4 through 4.9 shall be used to determine the design-basis criteria.

R4.3—Potentially dangerous structural conditions

R4.3.2 Demand/capacity ratios are used to quantify the adequacy of the member or structure. The threshold demand/capacity ratios determine when different levels of intervention may be required. For each demand/capacity ratio, this code provides direction on how the demand and capacity are determined. Demands may be determined based upon loads associated with current building codes (\( U_i \) as defined above) or loads specified during the original design of the structure (\( U_o \) as defined in Section 4.5.1). The calculated capacity of the structure will vary depending upon the condition of the structure and extent of evaluation used to confirm as-built properties of the structure.

In assessing potentially dangerous structural conditions, the demand of Eq. (4.3.2) combines current building code nominal gravity loads (dead, live and snow) with lateral loads from fluid, soil and wind (excluding seismic forces), using the factored load combinations of ASCE/SEI 7. A demand/capacity ratio greater than 1.5, calculated using Eq. (4.3.2), represents a condition with limited to potentially no margin of safety against failure for ASCE/SEI 7 loads (Stevens and Kesner 2016).

In the assessment of potentially dangerous structural conditions, the licensed design professional should determine if it may be appropriate to include structural redundancies, alternate load paths, primary and secondary supporting elements, redistribution of loads, collapse mechanisms, reduced live loads, measured displacements (sagging, listing, leaning and tilting), second-order effects, and other loads specific to the structure, such as drifting snow, self-straining loads, ice, and floods. References for potentially dangerous structural conditions are Galambos et al. (1982), Ellingwood et al. (1982), and Ellingwood and Ang (1972). These references provide guidance in judging acceptable performance.
4.3.3 Assessment criteria for potentially hazardous structural conditions of concrete structures for seismic loads, unless addressed by the authority having jurisdiction, are limited to potentially hazardous conditions associated with Structural Performance Level, Collapse Prevention of structures in Seismic Design Category D, E, and F of ASCE/SEI 7 using Earthquake Hazard Level, BSE-1E, and shall be determined using ASCE/SEI 41 and this Code. The design-basis criteria for retrofit design and construction to address potentially hazardous seismic conditions in concrete structures shall be this Code and ASCE/SEI 41.

4.4—Substantial structural damage

4.4.1 Substantial structural damage shall be assessed and rehabilitated as referenced in Table 4.1.4.

4.5—Conditions of deterioration, faulty construction, or damage less than substantial structural damage with strengthening

4.5.1 The demand/capacity ratio of the member, system, or structure of the work area shall be evaluated using the original building code demand \( U_o \) with nominal loads, factored load combinations, and capacities of the original building code to determine if the demand/capacity ratio exceeds 1.0, as shown in Eq. (4.5.1).

\[
U_o/\phi R_{cn} > 1.0 \quad (4.5.1)
\]

In Eq. (4.5.1), \( U_o \) is the strength design demand determined by using the nominal loads and factored load combinations of the original building code. \( \phi R_{cn} \) is the capacity adjusted by the reduction factor (\( \phi_o \)) of the original building code.

If \( U_o/\phi R_{cn} \) is greater than 1.0, then strengthening repairs are required and shall be permitted to restore the structural capacity required by the original building code.

Repair of the existing concrete structure shall be permitted to restore a member, system, or structure of the work area to the capacity of the original building code based on the material properties of the original construction. New concrete members and connections to existing construction shall provide basic probability theory and concepts for an evaluation using the specific details of the demand as it relates to the capacity with the strength reduction factors of Section 5.3 for new concrete structures.

R4.3.3 Compliance with ASCE/SEI 41 for Structural Performance Level, Collapse Prevention using an applicable Earthquake Hazard Level, BSE-1E should be reviewed and approved by the local authority having jurisdiction for the assessment of potentially hazardous seismic conditions of concrete structures. Assessment of potentially hazardous seismic conditions for concrete structures is not required for structures in regions of low or moderate seismicity. If no requirements for potentially hazardous seismic structural conditions are provided by the local authority having jurisdiction, the licensed design professional should refer to ATC-78, the IEBC and ASCE/SEI 41 appendices for guidance.

R4.5—Conditions of deterioration, faulty construction, or damage less than substantial structural damage with strengthening

R4.5.1 Concrete structures with damage less than substantial structural damage, deterioration, or containing faulty construction have historically been restored to the strength of the original building code.

The demand/capacity ratio limit of 1.0 as provided in this section allows strengthening repair that restores the structural reliability of the existing structure to the level prior to damage and deterioration when that repair is greater than that intended in the original building code.

Historical performance is often an acceptable indicator of adequate safety if the structure has been subjected to known loads even if the demand in the original building code was significantly different from the current building code.

If the capacity of the structure is not in question, such as indicated by the commentary provisions of R1.7, assessment checks are not required.
comply with provisions of 4.1.5. If \( U_o/\phi R_{cn} \) is 1.0 or less, then strengthening repairs are not required.

4.5.2 An alternative assessment criteria shall be permitted when approved by authority having jurisdiction using engineering principles for the member, system, or structure of the work area of the existing structure.

R4.5.2 An assessment criterion other than the current building code or ASCE/SEI 41 may be used. The references of R4.3.2 should be considered in the selection of applicable assessment criterion. Beyond using the current building code, the assessment criteria should address if the demand or capacity of the original structure or member is significantly inconsistent with current standards resulting in unacceptable structural safety. An increase in load intensity; added loads; changes in load factors, strength reduction factors, or load combinations; modification of analytical procedures; or changes in the determined capacity between the original and current building code (such as a change from allowable stress design [ASD] to strength design) should lead the licensed design professional to question the applicability of using the original building code for the assessment of an existing structure. Engineering principles used to determine acceptable structural safety are to use either a probabilistic evaluation of loads and capacities to show adequate structural reliability indices or an evaluation procedure using demand/capacity ratios that are derived from the basic engineering principles as presented in current standards.

An assessment criterion for a structure that has damage less than substantial structural damage, deterioration, or faulty construction that is based on the demand/capacity ratio threshold of 1.05 using the original building code or 1.1 using the current building code is the following:

- If the current building code demand \((U_c)\) exceeds the original building code demand \((U_o^*)\) increased by 5 percent \((U_c > 1.05U_o^*)\), check the demand/capacity ratio using the current building code demand \((U_c)\) to determine if it exceeds 1.1, as shown in Eq. (R4.5.2a).

\[
U_c/\phi R_{cn} > 1.1 \quad \text{(R4.5.2a)}
\]

If the demand/capacity ratio exceeds 1.1, then that system or member should be strengthened using the current building code demand. If the demand/capacity ratio does not exceed 1.1, then no strengthening is required.

- If the current building code demand \((U_c)\) does not exceed the original building code demand \((U_o^*)\) increased by 5 percent \((U_c \leq 1.05U_o^*)\), check the demand/capacity ratio using the original building code demand \((U_o^*)\) to determine if it exceeds 1.05, as shown in Eq. (R4.5.2b).

\[
U_o^*/\phi R_{cn} > 1.05 \quad \text{(R4.5.2b)}
\]

If the demand/capacity ratio exceeds 1.05, then that system or member strength should be restored using the original building code demand. If the demand/capacity ratio does not exceed 1.05, then strengthening is not required.

In this assessment criterion, the strength reduction factors \((\phi)\) of Section 5.3 or 5.4 shall be applied in both Eq. (R4.5.2a) and (R4.5.2b).
CODE

4.5.3 If the concrete design criteria of the original building code only used allowable stress design, an alternate to using 4.5.2 strength design criteria is to evaluate the demand/capacity ratio of the member, system, or structure of the work area based on allowable stress design load combinations for demand \( U_s \) and resistance calculated using allowable stresses \( R_a \) as shown in Eq. (4.5.3).

\[
U_s / R_a > 1.0 \quad (4.5.3)
\]

If the demand/capacity ratio exceeds 1.0, then strengthening repairs are required and shall be permitted to restore the structural capacity as required by the original building code. If the demand/capacity ratio is 1.0 or less, then strengthening repairs are not required.

Repair of the existing concrete structure shall be permitted to restore a member or system of the work area to the capacity of the original building code based on the material properties of the original construction. New concrete members and connections to existing construction are part of the repair and shall comply with provisions of 4.1.5.

4.5.4 Existing structures other than those to be strengthened per 4.3 through 4.5 shall use 4.6 through 4.9 to determine the design-basis criteria.

4.6—Conditions of deterioration, faulty construction, or damage less than substantial structural damage without strengthening

4.6.1 If less-than-substantial structural damage is present, structures damaged, deteriorated, or containing faulty construction that do not require strengthening in accordance

COMMENTARY

The current building code strength design demand \( U_c \) combines current building code nominal gravity loads (dead, live, and snow) with lateral loads from fluid, soil, wind, and seismic using the factored load combinations of ASCE/SEI 7. The original building code strength design demand \( U_o^* \) combines original building code nominal gravity loads (dead, live, and snow) and lateral loads from fluid, soil, wind, and seismic using the factored load combinations of ASCE/SEI 7.

It may be appropriate to consider detailing requirements for ductility when considering seismic resistance, redistribution of internal member forces, reduced live loads, measured displacements (sagging, listing, leaning, and tilting), second-order effects, and other loads specific to the work area of the structure, such as drifting snow, lateral earth and fluid pressures, self-straining loads, ice, and floods.

The use of structure-specific data is acceptable, if substantiated by the licensed design professional. For these assessment criteria, the demand/capacity ratio provisions in R4.5.2a may be used in the assessment, whether the current building code demand does or does not exceed the original building code demand increased by 5 percent.

R4.5.3 Before the “Building Code Requirements for Reinforced Concrete (ACI 318-63)” in 1963, the design of reinforced concrete structures was based upon allowable stress or working stress design principles. Original building code demands should include nominal gravity loads (dead, live, and snow) and lateral wind forces or seismic forces using the load combinations of original building code. Displacements (sagging, listing, leaning, and tilting), second-order effects, and other loads specific to the work area of the structure, such as drifting snow, lateral earth pressures, self-straining loads, ice, and floods should be considered.

Using allowable stress design is inconsistent with the reliability principles of current strength design provisions. To adequately address current safety levels, consideration should be given to verification using strength design provisions of 4.5.2. It may be appropriate to consider detailing requirements for ductility when considering seismic resistance.

R4.6—Conditions of deterioration, faulty construction, or damage less than substantial structural damage without strengthening

R4.6.1 Serviceability requirements including deflection limits and crack control reinforcement in the current building code are not requirements of this code, but should be considered in the assessment and repair of existing structures.
with 4.5 shall use Chapters 7 through 10 of this code as the design-basis criteria.

4.7—Additions
4.7.1 The existing structure shall be assessed and rehabilitated in accordance with structural requirements of the IEBC per Table 4.1.4 for Additions.

4.8—Alterations
4.8.1 The existing structure shall be assessed and rehabilitated in accordance with structural requirements of the IEBC per Table 4.1.4 according to Alteration level 1, 2, or 3.

4.9—Change of occupancy
4.9.1 The existing structure shall be assessed and rehabilitated in accordance with structural requirements of the IEBC per Table 4.1.4 for changes of occupancy.

R4.8—Alterations
R4.8.1 Alterations in this section exclude the remedial work of 4.3 through 4.6.
CHAPTER 5—LOADS, FACTORED LOAD COMBINATIONS, AND STRENGTH REDUCTION FACTORS

5.1—General

5.1.1 If this code is part of the design-basis code, the load factors, load combinations, and strength reduction factors in this chapter shall be used for the assessment of the existing structure and the design of rehabilitation.

5.1.2 It shall not be permitted to use load factors and load combinations from the original building code with strength reduction factors from this chapter. It shall not be permitted to use load factors and load combinations from this chapter with strength reduction factors from the original building code.

5.1.3 For work areas subjected only to construction activity and not subjected to design occupancies, it shall be permitted to determine factored loads on only those areas in accordance with ASCE/SEI 37.

5.1.4 When assessing an existing structure, consideration shall be given to effects caused by loads or imposed deformations that the structure is subjected to, if required by the authority having jurisdiction, even if such effects may not have been specified in the original building code.

5.2—Load factors and load combinations

5.2.1 Design of rehabilitation shall account for existing loads and imposed deformations of the structure; the effects of load redistribution due to damage, deterioration, or load removal; and the sequencing of load application, including construction and shoring loads, during the rehabilitation process.

5.2.2 Structural assessment shall consider whether the design strengths of members and connections in the work area are sufficient to resist the factored load combinations required by this Code. In the rehabilitation design, the structural members and connections shall have design strengths at least equal to the required strengths calculated for the factored load combinations as required by this Code.

5.2.3 Required strength $U$ shall be at least equal to the effects of factored load combinations as specified in the design-basis code.

5.2.4 Required strength $U$ shall include internal load effects due to reactions induced by prestressing with a load factor of 1.0.

R5—LOADS, FACTORED LOAD COMBINATIONS, AND STRENGTH REDUCTION FACTORS

R5.1—General

R5.1.1 Load factors, load combinations, and strength reduction factors are intended to achieve consistent acceptable levels of safety among all the structural elements in a system. They are obtained through rational design code calibration procedures that consider the accuracy of the strength prediction models and on the expected loads during the design service life of the structure.

R5.1.2 Mixing of load factors and load combinations from one code with strength reduction factors from a different code may result in an inconsistent level of safety.

R5.1.3 This provision permits the less stringent loads and load factors in ASCE/SEI 37 to be applied for areas designated for construction activity and not subjected to design occupancies.

R5.1.4 Examples of such loads include vibration or impact loads. Examples of such imposed deformations include unequal settlement of supports, sagging, and listing, leaning and tilting, and those due to prestressing, shrinkage, temperature changes, and creep.

R5.2—Load factors and load combinations

R5.2.2 The basic requirement for strength design or assessment is expressed as:

\[
\phi(R_n) \geq U
\]

The design strength is the nominal strength multiplied by the strength reduction factor $\phi$.

R5.2.3 The required strength $U$ is expressed in terms of factored loads, which are the product of specified nominal loads multiplied by load factors.
5.2.5 For post-tensioned anchorage zone design or evaluation, a load factor of 1.2 shall be applied to the maximum prestressing reinforcement jacking force.

5.3—Strength reduction factors for rehabilitation design

5.3.1 Design strength provided by a member, its connections to other members, and its cross sections, in terms of flexure, axial load, shear, and torsion, shall be taken as the nominal strength calculated in accordance with requirements and assumptions of this code, multiplied by the strength reduction factors $\phi$ in 5.3.2 and 5.3.4.

5.3.2 The strength reduction factor $\phi$ shall be shown in Table 5.3.2.

*Applies when the steel tensile strain at member failure exceeds 2.5$\varepsilon_y$, where $\varepsilon_y$ is the yield strain of the tensile reinforcement.
†Applies when the steel tensile strain at member failure does not exceed $\varepsilon_y$. For sections in which the net tensile strain in the extreme tension steel at nominal strength is between the limits for compression-controlled and tension-controlled sections, linear interpolations of $\phi$ shall be permitted.
‡Spirals shall satisfy 10.7.6.3, 20.2.2, and 25.7.3 of ACI 318-14.
§Does not apply to post-tensioned anchorage zones or elements of strut-and-tie models.

If an evaluation of members is based on historical material properties as given in Tables 6.3.2a through 6.3.2c, the $\phi$-factors not exceeding those in 5.3 shall apply.

For flexure, compression, shear, and bearing of structural plain concrete, $\phi$ shall be 0.60.

5.5—Additional load combinations for structures rehabilitated with external reinforcing systems

5.5.1 For rehabilitation achieved with external reinforcing systems that are susceptible to damage by vandalism or impact, the required strength of the structure without rehabilitation shall equal or exceed the effects of the load combinations specified in 5.5.2. The performance of externally reinforced elements subjected to fire shall be evaluated using the load combinations specified in 5.5.3.

5.5.2 The additional load combinations specified in this section are intended to ensure adequate strength should the external reinforcing system be sufficiently damaged to become ineffective. External reinforcing systems should be evaluated to determine if they are susceptible to damage from accidental vehicular impact or vandalism. Alternately, the rehabilitation measures may include physical design features that protect the external reinforcing system from these types of damage. The requirements of this section are not intended for the assessment of the effect of blast loadings, blast effects or a generalized assessment of extraordinary events on structures.

The requirements of this section are not intended for the design of structures that are exposed to elevated tempera-
5.5.2 For external reinforcing systems susceptible to damage, the required strength of the structure without such external reinforcement shall satisfy Eq. (5.5.2a) and (5.5.2b)

\[
\phi R_n \geq 1.1D + 0.5L + 0.2S \quad (5.5.2a)
\]

\[
\phi R_n \geq 1.1D + 0.75L \quad (5.5.2b)
\]

where \(D\), \(L\) and \(S\) are the effects due to the dead, live, and snow loads, respectively, calculated for the rehabilitated structure; \(\phi\) is the strength reduction factor in 5.3 or 5.4, as applicable; and \(R_n\) is the nominal strength of the structural member computed using the material properties determined from Chapter 6, without the contribution of the external reinforcing system.

5.5.2.1 If the live load has a high likelihood of being a sustained load, the live load factor in Eq. (5.5.2a) and (5.5.2b) shall be increased to 1.0.

5.5.3 Structural members with external reinforcement shall satisfy Eq. (5.5.3)

\[
\phi_{ex} R \geq (0.9\ or\ 1.2)D + 0.5L + 0.2S \quad (5.5.3)
\]

where \(\phi_{ex} = 1.0\); \(R\) is the nominal resistance of the structural member, computed using the probable material properties during the fire event and considering the contribution of external reinforcement in accordance with Section 5.5.3.3; and \(S\) is the specified snow load. The dead load factor of 0.9 shall be applied when the dead load effect counteracts the total load effect.

5.5.3.1 Additional live loads incurred during a fire shall be considered, with a load factor of 1.0.

5.5.3.2 Internal forces and imposed deformations due to thermal expansion during the fire event shall be considered, with a load factor of 1.0, in determining the demands on the structural system.

\[\text{CODE}\]

\[\text{COMMENTARY}\]

\text{CODE REQUIREMENTS FOR ASSESSMENT, REPAIR, AND REHABILITATION OF EXISTING CONCRETE STRUCTURES (ACI 562-19)}

\text{American Concrete Institute Copyrighted Material — www.concrete.org}

\text{CODE COMMENTARY}

\text{R5.5.2} These load combinations are intended to minimize the risk of failure of the strengthened structural member in the case where, during normal operating conditions, the external reinforcement is damaged. Such damage may not be detected immediately and so the structure (or structural component) may remain in service until the damage is identified and addressed. The load factors for live and snow loads in Eq. (5.5.2a) correspond to the arbitrary point-in-time loadings specified in \text{ASCE/SEI 7}. Equation (5.5.2b) is compatible with \text{ACI 440.2R}.

\text{R5.5.2.1} Examples include library stack areas, heavy storage areas, warehouses, and other storage occupancies with a live load exceeding 100 lb/ft².

\text{R5.5.3} Equation (5.5.3) is intended to ensure that the repaired element will maintain sufficient strength, accounting for its probable reduced material properties due to elevated temperatures, during a fire event. If fire protection is applied to the repaired element, its effect on the external reinforcement and existing elements should be considered.

The design-basis code and \text{ACI 216.1} should be reviewed to determine the required duration of the fire event.

Equation (5.5.3) was developed from Eq. (2.5.1) of \text{ASCE/SEI 7-10} and is limited to the evaluation of fire effects on structures with external reinforcement. Guidance on computing the structural effects caused by the fire event is provided in 5.5.3.1 and \text{R5.5.3.1}.

Strength of the affected portion of the structure during a fire event should be based on reduced steel and concrete strengths. Guidance concerning probable material properties during a fire event may be obtained from \text{ACI 216.1}.

\text{R5.5.3.1} Live loads associated with firefighting operations may include wetting of the building contents, which can be idealized as a live load of 20 lb/ft².

\text{R5.5.3.2} Thermal expansion of a member during a fire event will generate internal thrust forces if that expansion is restrained. The generated thrust force, while potentially large, is considerably less than that computed using conventional elastic properties and thermal expansion coefficients. This thrust may increase the moment capacity and the corresponding fire endurance of the restrained member.

Procedures for calculating thermal induced thrust forces can be found in \text{NIST (2010)} and \text{Buchanan (2001)}. \text{PCI (2010)} provides methods for determining (a) the magnitude and location of the thrust generated by a given fire tempera-

CHAPTER 6—ASSESSMENT, EVALUATION, AND ANALYSIS

6.1—Structural assessment

6.1.1 A structural assessment shall be performed if required per 1.7.5. The structural assessment shall comprise 1) an investigation to establish the in-place condition of the structure in the work area, including environment, geometry, material strengths, reinforcing-steel sizes and placement, and signs of distress; 2) an evaluation to define the causes of distress and criteria for selection of rehabilitation solution(s); and 3) development of appropriate rehabilitation strategies.

6.2—Investigation and structural evaluation

6.2.1 An investigation and structural evaluation shall be performed when there is a reason to question the capacity of the structure in the work area and insufficient information is available to determine if an existing structure is capable of resisting design demands.

6.2.2 Where repairs are required to an individual member or connection in a structure, determine if similar conditions exist beyond the work area also require evaluation.

6.2.3 An investigation shall document conditions as necessary to perform an evaluation of the structure in the work area.

R6—ASSESSMENT, EVALUATION, AND ANALYSIS

R6.1—Structural assessment

R6.1.1 Field investigations in support of the structural assessment may include visual observations, destructive testing, and nondestructive testing (NDT). Areas of known deterioration and distress in the structural members should be identified, inspected, and recorded as to the type, location, and degree of severity. Investigation procedures are referenced in ACI 201.1R, ACI 228.1R, ACI 228.2R, ACI 364.1R, ACI 437R, ASCE/SEI 11, ASCE/SEI 41, and FEMA P-154. The affected structural members are not only members with obvious signs of distress but also contiguous members and connections in the structural system.

The data gathered to determine the existing capacity should include the following:

1) The effects of material deterioration, such as loss of concrete strength from chemical attack; freezing and thawing
2) Loss of steel area due to corrosion or other causes
3) Missing or misplaced reinforcement
4) Effects of damaging events, such as earthquakes or fire

The effect of deterioration on the ductility of the member should be considered in the evaluation. The strength or serviceability of a member or structure may be compromised by spalling, excessive cracking, large deflections, or other forms of damage or deterioration. Seismic evaluation references for undamaged buildings include FEMA P-58, FEMA P-154 and ASCE/SEI 41 and for damaged buildings include FEMA 306 and FEMA 307.

Where the as-built conditions and properties of historical buildings require evaluation and rehabilitation, care should be taken to minimize the impact of repair design and investigation procedures (U.S. Department of the Interior 1995).

R6.2—Investigation and structural evaluation

R6.2.2 If there is no evidence of damage, distress or deterioration of similar members or connections elsewhere in the work area that required repair, there is no need to perform an evaluation of similar members unless potentially dangerous conditions are present. Such conditions may be a concern if there are significant variances from the original design intent such as lower-strength concrete or insufficient reinforcement. In addition, if the similar members are in an environment that could foster deterioration, then evaluation of these members may be necessary to determine if strengthening or durability enhancements may be required.

R6.2.3 Conditions which may need to be documented include (a) through (g):
6.2.4 When an analysis is required, the analysis shall be performed in accordance with Section 6.5 and the structural evaluation shall consider the following items.

(a) As-measured structural member dimensions including the reinforcement configuration
(b) The presence and effect of alterations to the structural system
(c) Loads, occupancy, or usage different from the original design
(d) In-place material properties in accordance with 6.3

6.3—Material properties

6.3.1 Concrete compressive strength and steel reinforcement yield strength shall be determined for the structure if a structural evaluation is required. Nominal material properties shall be determined by (a), (b) or (c):

(a) Available drawings, specifications, and previous testing documentation
(b) Historical material properties in accordance with 6.3.2
(c) Physical testing in accordance with 6.4

R6.2.4 The size, number, and location of the reinforcement may be needed to determine member strength. Nondestructive testing methods, including but not limited to ground-penetrating radar (GPR) and ferromagnetic testing, may be used to determine the location and spacing of reinforcement. These methods may require destructive confirmation. Additional guidance is provided in ACI 228.2R.

R6.3—Material properties

R6.3.1 The construction documents may not represent as-built conditions. Therefore, the evaluation of material properties may require verification by material testing to confirm that the material properties obtained from record documents are representative.

Additional factors and characteristics affecting materials that may be required to be evaluated include:

(a) Ductility based on the mechanical characteristics of the component materials.
(b) Presence of corrosion of embedded steel reinforcement, including carbonation, chloride intrusion, corrosion-induced spalling
(c) Presence of other deterioration, such as alkali-silica reaction, sulfate attack, delayed ettringite formation, or other chemical attack
(d) Deterioration due to cyclic freezing and thawing
(e) Deterioration of stiffness and strength due to bar slip in cracked sections and joints damaged in seismic events

Other tests for material properties, including petrographic examination, are used.
6.3.2 If available drawings, specifications, or other documents do not provide sufficient information to characterize the material properties, it shall be permitted to determine such properties without physical testing from the historical data provided in Tables 6.3.2a through 6.3.2c.

Note: Adopted from ASCE/SEI 41.

An entry of “X” indicates the grade was available in those years.

The terms “structural,” “intermediate,” and “hard” became obsolete in 1968. Hard grade does not correspond to metallurgical hardness.
6.3.3 It shall be permitted to determine material properties through testing in accordance with 6.4.

6.3.4 The material properties provided in the original construction documents or material test reports shall be permitted to be used unless known deterioration that can affect performance has occurred.

6.3.5 If historic data are not given in either Table 6.3.2b or 6.3.2c, the historic default value for yield strength $f_y$ shall be taken as 33,000 psi.

6.4—Test methods to quantify material and member properties

6.4.1 General

6.4.1.1 Destructive and nondestructive test methods used to obtain in-place mechanical properties of materials and member properties shall be in accordance with this section. Compressive strength of sound concrete shall be determined.

Table 6.3.2c—Default tensile and yield strength properties of steel reinforcement for various ASTM specifications and periods

Note: Adopted from ASCE/SEI 41.

An entry of “X” indicates the grade was available in those years.

The terms structural, intermediate, and hard became obsolete in 1968. Hard grade does not correspond to metallurgical hardness.

ASTM steel is marked with the letter W.

Rail bars are marked with the letter R.

Bars marked with “s!” (ASTM A616-96) have supplementary requirements for bend tests.

ASTM A706 has a minimum tensile strength of 80 ksi, but not less than 1.25 times the actual yield strength.
by taking and testing core samples or by a combination of cores and by the use of site specific nondestructive testing. Steel reinforcement properties shall be determined by removal of reinforcement samples and destructive testing.

6.4.1.2 The locations and numbers of material samples shall be sufficient to define the material properties of the structural element of concern. The number of samples shall be determined during evaluation.

6.4.2 Core sampling of concrete for testing

6.4.2.1 It shall be permitted to determine the compressive strength of sound concrete by taking cores from the members being evaluated. Steel reinforcement shall be located before locating the cores to be extracted.

6.4.3 Concrete

6.4.3.1 The cores shall be selected, removed, and tested in accordance with ASTM C42 and ASTM C823. The equivalent specified concrete strength \( f_{\text{eq}} \) shall be calculated by:

\[
f_{\text{eq}} = 0.9 \bar{f}_c \left[ 1 - 1.28 \left( \frac{k V^2}{n} \right) + 0.0015 \right] \quad (6.4.3.1)
\]

where \( \bar{f}_c \) is the average core strength, as modified to account for the diameter, length to diameter ratio and moisture condition of the core (following ASTM C42 procedures); \( V \) is the coefficient of variation of the core strengths (a dimensionless quantity equal to the sample standard deviation divided by the mean) and \( n \) is the number of cores.

R6.4.1.2 Review of available records from the original construction may be used to guide testing. Evaluation, historical research, and documentation of the geometry, material properties, and detailing used in the construction are invaluable and may be used to reduce the amount of required in-place testing. The data gathered to determine strength should include any effects of material deterioration, such as loss of concrete strength from chemical attack and loss of steel area due to corrosion. The impact of deterioration on the expected strength and ductility of the section also should be considered in the evaluation.

The minimum number of tests is influenced by the data available from the original construction, the type of structural system, the desired accuracy, and the quality and condition of the in-place materials. The focus of the prescribed material testing should be on the principal structural members and specific properties needed for analysis. The licensed design professional should determine the appropriate number and type of testing needed to evaluate the existing conditions.

Care should be taken in selecting the location for sampling concrete. Core drilling should minimize damage of the existing reinforcement and should generally occur at locations where the coring will least affect the member strength.

R6.4.2 Core sampling of concrete for testing

R6.4.2.1 NDT may be used to locate existing reinforcement and to avoid damage to reinforcement during coring. Guidelines for core sampling and evaluating core strength data are given in ACI 214.4R. The presence of reinforcement or other foreign material, such as conduit or wood, may adversely affect the test strength of the concrete and cores containing such foreign material should not be used for strength determination. See ASTM C42/C42M Section 5.1.3 and Note 8 for additional information.

R6.4.3 Concrete

R6.4.3.1 The equivalent specified strength determined using this procedure can be used in strength equations with the strength reduction factors from Chapter 5. This approach is specified in the Canadian Highway Bridge Design Code (CAN/CSA S6-14) and is based on the approach proposed by Bartlett and MacGregor (1995). Equation (6.4.3.1) is a simplification of criteria given in ACI 214.4R that gives similar results because it includes the strength correction factors for length-to-diameter ratio, core diameter, and drilling damage. The strength value obtained using this procedure is an estimate of the 13 percent fractile of the in-place concrete strength at a confidence interval of 90 percent, based on the field data collected by Bartlett and
by the mean); \( n \) is the number of cores taken; and \( k_c \) is the coefficient of variation modification factor, as obtained from Table 6.4.3.1.

Table 6.4.3.1—Concrete coefficient of variation modification factor \( k_c \)

6.4.3.2 Nondestructive strength testing to evaluate in-place strength of concrete shall be permitted if a valid correlation is established with core sample compressive strength test results and nondestructive test results. Quantifications of concrete compressive strength by NDT alone shall not be permitted as a substitute for core sampling and testing.

6.4.4 Steel reinforcement

6.4.4.1 If the original construction documents are not available and if the properties of the reinforcing bars are unknown, historical values provided in 6.3.2b and 6.3.2c shall be permitted in place of testing. If the grade of material is unknown, the lowest grade provided in Table 6.3.2b for a given historic period shall be used.

6.4.5 Reinforcement sampling and testing

6.4.5.1 Coupon samples used for the determination of the yield and tensile strength for steel reinforcement shall be obtained in accordance with ASTM A370. A minimum of three sample coupons, taken from different segments of reinforcement shall be obtained from the members being evaluated.

MacGregor (1995). When a different strength fractile or confidence interval is required, the methods presented in ACI 214.4R may be applicable.

The core samples, tested per ASTM C42/42M, are expected to be moisture conditioned following the procedure in the ASTM standard. The correction factors in ASTM C42/42M were developed for lightweight and normal weight concrete with a compressive strength between 2,000 and 6,000 psi (14 MPa to 42 MPa). Core samples are assumed to have a maximum length-to-diameter ratio of 2.1. Bartlett and MacGregor (1994a) discuss the effect of higher compressive strengths on the length-to-diameter ratio.

ASTM C42/42M procedures require a minimum core diameter of 3.70 in. (94 mm), smaller diameter cores are likely to have more variability and a lower strength (Bartlett and MacGregor 1994b).

When the testing requirements of ASTM C42/42M are not met, the user should consult ACI 214.4R.

R6.4.3.2 ACI 228.1R provides information on NDT methods for evaluation of concrete compressive strength and development of statistical correlations between NDT and core test results.

R6.4.4 Steel reinforcement

R6.4.4.1 The age of the structure may be known but the grade of reinforcement may not be known. In this case, the lowest grade of reinforcement corresponding to the structure’s age should be used. If the date of original construction is unknown, the lower bound value of \( f_y \) equal to 33,000 psi may be used instead of testing, provided it is conservative. In some instances, assuming higher yield strengths may be more conservative. Where the demand on one member is governed by the capacity of a connected member, it is appropriate to assign higher yield strengths to the connected member. For example, in seismic analysis at beam column joints, the moment strength of the columns should exceed the moment strength of the beams. When assessing this requirement it is more conservative to assume a higher yield strength for the beam reinforcement than for the column reinforcement.

R6.4.5 Reinforcement sampling and testing

R6.4.5.1 Often, the steel reinforcement in a structure is of a common grade and strength. Occasionally, more than one grade of steel is used, for example, smaller diameter (No. 3 and 4) stirrups and other complex bent bars were often fabricated with lower strength material than the longitudinal bars.
6.4.6 The equivalent specified yield strength $f_{yeq}$ of reinforcement used for analysis shall be calculated by

$$f_{yeq} = (\bar{f}_y - 3500) e^{(-1.3k_sV)} \quad (6.4.6)$$

where $\bar{f}_y$ is the average yield strength value from the tests, in psi; $V$ is the coefficient of variation determined from testing; $n$ is the number of strength tests; and $k_s$ is the steel coefficient of variation modification factor, as obtained from Table 6.4.6.

Table 6.4.6—Steel coefficient of variation modification factor $k_s$

6.4.7 If the properties of the connector steel are unknown, strength shall be determined by (a), (b), or (c):

(a) Testing of coupons taken from the connector steel.

(b) Documentation giving connector steel properties in the original construction documents.

(c) Use of historic default values in accordance with 6.3.6.

6.4.8 Coupon specimens for the determination of yield and tensile strengths of structural steel shall be tested in accordance with ASTM A370. A minimum of three specimens shall be taken from representative elements.

The equivalent specified yield strength $f_{yeq}$ of each specimen shall be its reported yield strength. The $f_{yeq}$ used for analysis shall be calculated by

$$f_{yeq} = (\bar{f}_y - 4000) e^{(-1.3k_sV)} \quad (6.4.8)$$

R6.4.6 The equivalent specified yield strength determined using this procedure can be used in strength equations with the strength reduction factors from Chapter 5. The yield strength value obtained using this procedure is an estimate of the 10 percent fractile of the static steel strength. It is assumed that the yield strength measured during a coupon test exceeds the static yield strength by 3500 psi. This approach is specified in the Canadian Highway Bridge Design Code (CAN/CSA S6-14).

The factors in Table 6.4.6 reflect the uncertainty of the sample standard deviation for a small sample size. They are the 95 percent one-sided tolerance limits on the 10 percent fractile, and they have been reduced by a constant factor to be equal to 1.0 for $n = 30$ specimens.

R6.4.7 The historic default value is obtained from ASCE/SEI 41.
where \( f_y \bar{f} \) is the average yield strength value from tests, in psi; 
\( V \) is the coefficient of variation determined from testing; \( n \) is the number of strength tests; and \( k_s \) is the steel coefficient of variation modification factor, as obtained from Table 6.4.6.

6.4.9 The sampling of prestressing steel reinforcement for strength testing shall be required if strength and historical data are not available. Testing of the prestressing reinforcement shall be in accordance with ASTM A1061/1061M.

6.4.10 If welding of existing reinforcement is required, carbon equivalent shall be determined in accordance with AWS D1.4/D1.4M.

6.5—Structural analysis of existing structures

6.5.1 The gravity and lateral-force-resisting structural systems shall be analyzed when required using loads and load combinations determined in accordance with this code that produce the maximum effects on the existing members being evaluated.

6.5.2 Analysis of the structure shall use accepted engineering principles that satisfy force equilibrium and the principles of compatibility of deformations and strains.

6.5.3 Analysis shall consider material properties, member geometry and deformation, lateral drift, duration of loads, shrinkage and creep, and interaction with the supporting foundation.

6.5.4 Members shall be analyzed considering the effect of material deterioration, bond loss, and the redistribution of forces in members and in the structural system as a whole.

6.5.5 Analysis shall consider the load path from the load application through the structure to the foundation. Three-dimensional distribution of loads and forces in the complete structural system shall be considered unless a two-dimen-

R6.5—Structural analysis of existing structures

R6.5.1 Structural evaluation and analyses are conducted to verify strength and serviceability. The analytical methods of 6.5 are used with factored loads to determine strength requirements for a combination of flexure, shear, torsion, and axial loads of pertinent structural members. A service-load analysis may be required to evaluate serviceability issues such as deflection and cracking.

R6.5.2 Analysis of the structure shall use accepted engineering principles that satisfy force equilibrium and the principles of compatibility of deformations and strains.

R6.5.3 The licensed design professional is responsible for determining the appropriate method of analysis. Appropriate methods include linear elastic analysis, nonlinear analysis, and other traditionally accepted engineering analysis methods. If a linear elastic analysis method is used, the effects of cracking, second-order and other nonlinear effects should be included in the analysis.

The analysis may include the effects of the size and member geometry to determine the forces on individual members of a structure. The analysis should consider external effects, including prestressing, material volume changes, temperature variations, and differential foundation movement.

R6.5.4 Member deterioration and damage may result in distribution of internal forces different than the distribution of forces of the original structural design. The strength and integrity of prestressed structures with damaged prestressing reinforcement requires careful consideration to assess the impact of the damage. The state of the structure should be accurately modeled to determine the distribution of forces. Redistribution of forces may be determined using material nonlinear analysis, by load tests described in ACI 437.2, or by linear analysis, which bounds the limits of redistributed forces.

R6.5.5 The evaluation of load effects requires consideration of both the load paths through the structure and how the forces are distributed in members.
sional analysis adequately represents the part of the structure being evaluated.

6.5.6 Analysis shall consider the effects of previous repairs and of any previous structural modifications on the behavior of the structure.

6.5.7 The analysis shall be based on available documentation, as-built dimensions, and the in-place properties of the structure including section loss. The determination of in-place material properties shall be in accordance with 6.3.

6.6—Structural serviceability

6.6.1 If serviceability problems are identified during the preliminary evaluation or the structural assessment, the licensed design professional shall perform a serviceability evaluation based on the existing geometry and properties of the structure.

6.6.2 The serviceability evaluation shall evaluate the structure for the intended use considering the existing geometry and properties of the structure, and shall consider such effects as existing floor levelness, support displacements, vibrations, and deflections.

6.7—Structural analysis for repair design

6.7.1 The structural analysis used for repair design shall consider the structural repair process. The analysis shall consider the effects of the sequence of load application and material removal during the anticipated phases of the evaluation and repair process.

R6.5.6 Modifications to structures in the form of repairs, alterations, or additions may affect the force distribution and load path in a structure.

R6.5.7 Available documentation may include original drawings, specifications, shop drawings, structural assessments, testing, and geotechnical reports. Deviations between the existing construction and construction documents are to be identified and recorded. If section loss has occurred, a more accurate analysis may be developed by direct measurement of the section, and by calculation of section properties based on actual conditions. Additional information may be obtained in ACI 364.10T.

R6.6—Structural serviceability

R6.6.1 Structural serviceability problems may include deflections, floor levelness, vibrations, leakage, or cracking. The data gathered to determine serviceability should include the effects of material deterioration, such as loss of concrete strength from sulfate attack or loss of steel area due to corrosion. Reference ACI 224.1R for additional information on cracking, including causation and repair.

R6.6.2 When specific concerns are raised regarding the serviceability of the structure, the effect of floor levelness, vibrations, and deflections on the structural performance should be investigated by the licensed design professional. The floor levelness, vibrations, and deflections should indicate (or be assessed to determine) if the performance of the structure is acceptable. Acceptable performance criteria will need to be established for an individual structure based upon the intended use of the structure.

The specific performance criteria and the intended function of the structure should be considered. Floor deflection criteria for new structures can be found in ACI 318. Vibration criteria are given in Fanella and Mota (2014).

Information on construction tolerances for new concrete construction is presented in ACI 117.1R; however, some of the tolerances only apply to measurement made during construction and therefore may not be appropriate to be used for existing completed construction. Refer to ATC Design Guide 1 (1999), Fanella and Mota (2014), and Wilford and Young (2006) for information on evaluation of vibration problems in concrete structures.

R6.7—Structural analysis for repair design

R6.7.1 The construction process may involve the application, removal and replacement of loads. The analysis needs to consider the effects of the application and removal of construction loads to determine the maximum loading during anticipated construction phases. The additional applied loads may be due to prestressing, vibration, material volume changes (such as creep and shrinkage, or tempera-
6.7.2 Structural analysis shall account for variations in material properties through member sections.

6.7.3 Section analysis shall use principles of mechanics and shall assume either (a), (b), or (c) as deemed appropriate by the licensed design professional:
- (a) Full composite action with no slip at interfaces between repair materials and existing materials
- (b) Separate action with full slip between repair and existing materials
- (c) Partial composite action with friction at interfaces between repair and existing materials

6.7.4 Seismic analysis of repaired structure

6.7.4.1 The interaction of structural members and nonstructural components that affect the response of the structure to seismic motions shall be considered in the analysis.

6.7.4.2 Existing, repaired, and added supplementary members assumed not to be a part of the seismic-force-resisting system shall be permitted, provided there is no adverse effect on the seismic-force-resisting system.

6.7.4.3 The analysis shall consider the structural configuration and material properties after repair.

R6.7.2 The intent of this section is to address differences in stiffness between repair material and existing substrate. In these situations, localized deformation may occur in the material with the lower modulus of elasticity, affecting the force distribution in the repaired structure.

R6.7.3 Depending on the repair construction process and the selection of repair materials, the repair materials and the existing concrete or reinforcement may not act compositely. The analysis should model the anticipated degree of composite action of the repaired structure. An example of partial composite behavior are beams that contain shear studs to develop nominal strength, yet lack bond between the overlay and substrate. In this situation, the overlay and substrate do not maintain strain compatibility.

R6.7.4 Seismic analysis of repaired structure

R6.7.4.3 Procedures for seismic rehabilitation of concrete buildings, including analysis, are provided in ASCE/SEI 41, which incorporates ACI 369R. These references provide details for forces, rehabilitation methods, analysis and modeling procedures, and seismic rehabilitation design. Additional references for repair of building damage by a seismic event and rehabilitation of concrete buildings include FEMA 308, FEMA 395 through FEMA 400, and FEMA 547.

R6.8—Strength evaluation by load testing

R6.8.1 Information obtained during a structural assessment may be insufficient to determine the strength or serviceability of deteriorated or repaired structural members. Structural condition assessments, including destructive testing, can provide some of the information required, but the costs for these assessments can be significant. Further, the results of a structural evaluation may still be inconclusive due to unknown effects of existing conditions or interaction with the repair. In such cases, load testing may provide the most effective means of verifying the strength of a structure or member. Load testing can also be a valuable tool for evaluating the effectiveness of structural repairs. For example, load testing, as defined in ACI 437.2, can be performed to determine if the service load deflection and cracking are acceptable.
6.8.2 Load tests shall be conducted in accordance with the monotonic or cyclic procedures in ACI 437.2.

6.8.3 The design professional is permitted to waive the $\ell_t/180$ deflection criteria in ACI 437.2.

6.8.4 If a member fails a cyclic load test, it shall be permitted to retest the member or structure in accordance with ACI 437.2. It shall be permitted to waive the maximum deflection limit ($\ell_t/180$) in ACI 437.2 that precludes a retest.

6.8.5 Model analysis shall be permitted to supplement calculations.

R6.8.2 If the strength of the structure being evaluated is limited by the strength of concrete, or the expected failure of the structure is controlled by shear or development of the reinforcement, the sustained load applied using the monotonic test allows greater time for widening and propagation of cracks, creep, and slip of reinforcement compared with the cyclic procedure.

R6.8.3 The $\ell_t/180$ deflection limit was included to provide an upper limit on the deflection of a member during a load test. The deflection limit may be waived by the design professional when the tested member is not damaged by large deflections or when the residual deflection criteria is satisfied.

R6.8.4 ACI 437.2 precludes a retest if the member exceeds a maximum deflection limit of $\ell_t/180$ (Section 6.4.4.2 in ACI 437.2). For consistency with the monotonic testing protocol, this $\ell_t/180$ limit is waived.

R6.8.5 This code permits model analysis to be used to supplement structural analysis and design calculations. Model analysis involves the construction and experimental testing of full or scale models of structure components, assemblages, or systems. Documentation of the model tests and subsequent interpretation should be provided with the related calculations. Model analysis should be performed by an individual having experience in this technique. References are provided in Harris and Sabnis (1999) and White (1970).
CHAPTER 7—DESIGN OF STRUCTURAL REPAIRS

7.1—General

7.1.1 Repaired structural elements and connections within the work area shall have design strengths at all sections at least equal to the required strengths calculated using the applied factored loads and internal forces in such combinations as required by this code.

7.2—Strength and serviceability

7.2.1 Repaired structures shall be designed to meet the strength requirements of the design-basis code.

7.2.2 Repair design and construction procedures shall consider loading, internal forces, and deformations in both the existing and repaired structure during the repair process.

7.2.3 When serviceability issues are identified consistent with Section 6.6, repairs to address serviceability issues shall be considered.

7.3—Behavior of repaired systems

7.3.1 Repairs to sections, components, reinforcement, connections of members, or systems shall be designed to be integrated with the existing structure, creating a structural system capable of resisting the design loads by sharing and transferring loads between repaired and existing elements.

7.3.1.1 Repairs incorporating new members shall be designed to be integrated with the existing structure, creating

R7—DESIGN OF STRUCTURAL REPAIRS

R7.1—General

Repair and rehabilitation, as defined in Chapter 2, are processes in which deficiencies and damage in a structure or member are corrected. The methods used to correct deficiencies and damage in structures will be the same for both repair and rehabilitation projects. For the purposes of this chapter, design requirements for repair and rehabilitation can be considered to be equivalent.

Durability requirements for repairs are in Chapter 8.

R7.1.1 Internal forces include those from externally applied loads and those from imposed deformations, from such actions as prestressing, shrinkage of repair materials, temperature changes, creep, unequal settlement of supports, and listing, leaning and tilting displacements.

R7.2—Strength and serviceability

R7.2.1 During the repair process, it may not be possible or practical to relieve existing stresses or deformations. Consideration should be given to the in-place internal forces and deformations present in the structure during the repair and the subsequent internal forces from the design loads that the repaired section will resist. Internal forces and deformations caused by existing loads may be locked in by the repair.

Analysis to evaluate the effects of structural modifications should verify that the strength is adequate and that serviceability conditions are met. As an example, creating a large opening in structural slabs may necessitate cutting reinforcement, which can significantly influence the global behavior of the structure. Supplementary strengthening may be required to address force redistribution that can exceed the existing strength of the affected elements. Slab punching shear strength should be evaluated for openings at the intersection of column strips to verify that the slab is adequate. This is especially critical near corner and edge columns where the slab shear stress is typically highest.

R7.2.3 Adequate stiffness needs to be determined on a project-specific basis and is a function of the structure type, the desired performance of the structure, and loading conditions and use.

R7.3—Behavior of repaired systems

R7.3.1.1 Repair of a structure may be achieved by improving the global behavior of the structure by adding
CODE

a structural system capable of resisting the design loads by sharing and transferring loads between new members and existing elements. The effect of the new members on the structure shall be evaluated according to the design-basis code.

COMMENTARY

new structural members that act integrally with the existing structural system or improving the behavior of the existing members. The design of the repair should consider connections of new members to the structure. Connections of new members should be designed to transfer design forces between new members and the structure.

Load sharing and load transfer should exist between the structure and the new members so that the assumed load path and force distribution can occur. The effects of adding new members on the global stiffness and force distribution should be considered.

New members may need to be separated from adjacent members to prevent or minimize interaction that may result in damage to adjacent portions of the structure. Transfer of forces between new and existing members should not compromise the performance of the structural system.

R7.3.2 Induced forces on the repaired member are shared between the existing member and the repair material or system. The repair should be designed to allow for transfer of forces between the two components.

The requirements for composite behavior between the repair and the member may vary depending on the type of repair (structural or nonstructural), the performance criteria at service, and the required strength at the ultimate limit states. While certain designs require composite behavior up to an ultimate limit state, others may be limited to service conditions. Composite behavior can be achieved by chemical bonding, mechanical means, or a combination thereof. The design should specify the repair materials and techniques that will develop the level of composite behavior to achieve the intended performance of the repaired member.

Specific reference is made to ACI 318-14, Sections 16.4 and 22.9, for force transfer requirements between new and existing concrete. Techniques other than shear-friction may be acceptable.

Design guidelines for bond of fiber-reinforced polymer (FRP) are provided in ACI 440.1R and 440.2R. Design provisions to achieve composite behavior with structural steel sections are provided in the “Specification for Structural Steel Buildings” (ANSI/AISC 360-16, Chapter I).

R7.3.3 Nonstructural repairs intended to improve durability or aesthetics may not require composite behavior under service loads. To prevent potentially dangerous conditions in the event of bond failure in a repair, the repair should encapsulate existing steel reinforcement. Alternately, the repair systems should be designed to provide redundant attachment of the repair material to the existing structure.

R7.4—Interface bond of cementitious repair materials

R7.4.1 The forces acting on the interface between cementitious repair materials and existing substrate can include tension, shear, or a combination of tension and shear depending on repair geometry and the applied loads. The
addition to internal forces resulting from restrained volume change to calculate the resultant interface stress demand \( (v_u) \) from the transfer of tension and shear.

7.4.1.1 Interface shear stress shall be designed based on

\[
v_{ui} \leq \phi v_{ni}
\]

(7.4.1.1)

where \( v_{ui} \) is nominal interface shear stress capacity and \( \phi \) is the strength reduction factor determined in accordance with 5.3.2.

7.4.1.2 Testing requirements for interface bond shall be in accordance with Table 7.4.1.2.

<table>
<thead>
<tr>
<th>( v_u )</th>
<th>Testing requirements</th>
</tr>
</thead>
<tbody>
<tr>
<td>Less than or equal to 30 psi</td>
<td>Bond integrity testing</td>
</tr>
<tr>
<td>Greater than 30 psi</td>
<td>Quantitative bond strength testing</td>
</tr>
</tbody>
</table>

7.4.2 If \( v_u \) does not exceed 30 psi, interface reinforcement shall not be required. Bond integrity testing as specified in the construction documents shall be performed.

R7.4.2 The 30 psi bond stress specified by this code is based on half of a nominal shear stress of 80 psi multiplied by the strength reduction factor in 5.3.2.

A properly prepared substrate is achieved by removing existing deteriorated, damaged, or contaminated concrete. The exposed sound concrete is then roughened and cleaned to allow for adequate bond of a repair material. ICRI Guideline No. 210.3 presents a discussion of achievable tensile bond strengths, suggests a minimum value of 100 psi for less critical applications, and indicates that tensile bond test values less than 175 psi that fail at the bond interface or superficially within the existing concrete substrate may indicate a partially damaged, contaminated, or otherwise inadequate bond surface. BS EN 1504-10 suggests minimum direct tension strengths of 100 psi for nonstructural repair and 175 to 215 psi for structural repairs. Interface reinforcement may be needed if sufficient interface capacity cannot be achieved through bond.

Bond integrity testing can consist of various nondestructive qualitative test methods such as sounding in accordance with ASTM D4580/D4580M, ground-penetrating radar or impact-echo described in ACI 228.2R or ICRI Guideline No. 210.4.

7.4.3 If \( v_u \) is between 30 psi and 60 psi, interface reinforcement is not required. Quantitative bond strength testing shall be performed to verify performance. Direct tension pull-off tests (ASTM C1583/C1583M) or other similar quantitative test methods shall be specified. The frequency of tests and acceptance criteria shall be specified, but the number of tests on a project shall be at least three (3).

R7.4.3 The 60-psi bond stress is based on a nominal shear stress of 80 psi multiplied by the strength reduction factor in 5.3.2.

On most concrete repair projects, testing to verify the bond of cementitious repair materials to the substrate is recommended as part of a quality assurance program. Quantitative bond strength testing is required when the bond stress exceeds 30 psi and interface reinforcement is not provided. ICRI Guideline No. 210.3 provides guidance on the number of tests.
7.4.4 If \( v_u \) exceeds 60 psi, interface reinforcement shall be provided.

7.4.5 If \( v_u \) is completely resisted by interface reinforcement, quantitative bond strength testing is not required.

7.4.6 Interface reinforcement shall be designed in accordance with ACI 318.

R7.4.5 This provision provides an alternative to bond strength testing.

R7.4.6 ACI 318 provides design provisions for horizontal shear transfer in composite concrete flexural members. Minimum reinforcement is required between horizontal shear stress of 60 and 375 psi (500 psi multiplied by strength reduction factor of 0.75). Where the required design horizontal shear stress is greater than 375 psi, Section 16.4.4.1 of ACI 318-14 requires design per Section 22.9 of ACI 318-14. For cases where there is a net factored tension across the interface, reinforcement should be provided and designed in accordance with ACI 318.

R7.4.7 Testing to verify the performance of the interface reinforcement to transfer horizontal shear can be performed in accordance with the recommendations contained in ACI 355.2 and 355.4. Specific requirements for testing of ties should be included in a quality assurance plan.

Direct tension testing of post-installed interface reinforcement is recommended to provide verification of the installation. Guidance for determining the number of tests and acceptance criteria of the direct tension testing is similar to principles used in developing direct tension pull-off testing requirements described in ICRI Guideline No. 210.3.
7.5—Materials

7.5.1 Materials in a structure shall be permitted to remain if such materials are performing satisfactorily.

7.5.2 Except as permitted by this code, materials permitted by the current building code for new construction shall be used. Like materials shall be permitted, provided they do not contain hazardous materials or other materials not permitted by the code for new construction.

7.5.3 Alternate materials shall be permitted following approval in accordance with 1.4.

7.5.4 Design of the repair system shall consider the properties and installation of the repair materials and systems. These include, but are not limited to: physical properties of the repair materials, type of application, adhesion, volume stability, thermal movement, durability, corrosion resistance, installation methods, curing requirements, and environmental conditions.

R7.5—Materials

R7.5.2 Hazardous materials include asbestos or other materials specifically prohibited by the current building code.

R7.5.4 Physical properties of repair materials include mechanical, chemical, and electrical properties. Documentation should be obtained for properties of each repair material. The stated properties should be verified that they satisfy the project requirements. ACI and ICRI provide guidelines for the selection of repair materials (ACI 301, ACI 318, ACI 503.5R, ACI 503.6R, ACI 506R, ACI 546.3R, ACI 549.1R, ICRI Guideline No. 320.2R, ICRI Guideline No. 320.3R, ICRI Guideline No. 330.1, and ICRI Guideline No. 340.1).

The design of a repair should consider the compatibility of the repair materials with the materials of the existing structure. Compatibility of repair materials and systems include volume stability, bond compatibility and durability, mechanical compatibility, and electrochemical and permeability compatibility. Generally, the intent is to use a repair material or repair system that has physical, mechanical, and other properties that are as close as possible to those of the parent material to provide long-term performance.

Individual repair materials may have different properties yet will perform satisfactorily when combined in a repair system. An example of this is where materials with differing thermal coefficients of expansion may be used, provided that the overall performance of the system is not affected by thermal changes.

Volume stability is often estimated as a change in the linear dimensions of the repair and should be considered in the design of a repair system. Autogenous shrinkage, chemical shrinkage, degree of restraint, environmental conditions, drying shrinkage, creep, thermal changes, moisture absorption, and other factors all affect volume stability. Experience has shown that volume change of repair materials has often been the cause of poor performance of repairs. Properties of repair materials should be selected considering volume stability relative to the volume stability of the existing concrete in order to reduce the probability of cracking caused by relative volume changes.

Volume stability is discussed in ACI 209R, ACI 209.1R, ACI 546.3R, and ICRI Guideline No. 320.2R.

Repair materials such as portland-cement concrete, portland-cement mortar, polymer-cement concrete, polymer concrete, shotcrete, fiber-reinforced concrete, resin-based materials, and similar products are commonly used. Repair...
### Code

**7.6—Design and detailing considerations**

**7.6.1** Repair design shall be based upon the member conditions in Chapter 6.

**7.6.2** *Concrete*—The in-place properties of the concrete, in accordance with Chapter 6, shall be used in the repair design.

**7.6.3** *Reinforcement*

**7.6.3.1** Reinforcement that is damaged or corroded shall be permitted to remain. The effective cross-sectional area of remaining reinforcement shall be permitted to be used in the repair design in accordance with the design-basis code. The effect of corrosion damage on development of steel reinforcement shall be considered. Where original deformations are no longer effective, reinforcing bars shall be considered as smooth bars.

**7.6.3.2** Repair design shall consider the location and detailing of the reinforcement in accordance with the assessment requirements of Chapter 6.

### Commentary

- Materials might not necessarily contain portland cement, but should be selected to achieve the necessary service, strength, and durability requirements.

- The selection of reinforcement material should consider the durability, performance at elevated temperatures, and ductility. Electrical and chemical reactivity between the reinforcement, the repair material, and the existing reinforcement should also be considered.

- Refer to ACI 440.1R for internal FRP reinforcement, ACI 440.2R for externally bonded FRP reinforcement, and ICRI Guideline No. 330.1 and ACI SP-66 for steel reinforcement.

- Required properties of the repair reinforcement should be specified in the construction documents. Specified reinforcement properties are dependent on the requirements of the repair and may include physio-chemical (for example, glass transition temperature, and coefficient of thermal expansion) as well as mechanical properties (for example, ultimate strength, tensile modulus, and ultimate elongation).

- Chloride penetration can cause corrosion that can lead to cracking and spalling. The depth of a spall reduces the effective area of concrete section. Degradation of the concrete affects the concrete compressive strength.

- Repair design should consider the in-place condition of the reinforcement, including the effective cross-sectional area of the reinforcing bars. The effective area is calculated using the remaining effective diameter of the reinforcing bar accounting for the loss of section due to corrosion. Further considerations may also include the location of the corroded areas, loss of confinement, the loss of bond, and the effect of corrosion on member strength. If the structure is fire damaged, steel reinforcement may be annealed, and the yield strength reduced. Refer to ACI 216.1 for additional guidance. Durability requirements related to corroded reinforcement are addressed in 8.4 and ACI 364.1R. CRSI (2014) provides information on older reinforcement systems.

- The location and detailing includes the horizontal and vertical positions, orientation, geometry of the reinforcement, development of reinforcement, and the presence of hooks and crossties. Field examination to locate reinforcement may be required. Guidance on evaluation techniques for reinforcement location is provided in Chapter 6.
7.6.3.3 Both existing and new reinforcement shall be adequately developed. Development length shall be permitted to be calculated based upon development in both the existing concrete and new materials and in accordance with the design-basis code.

R7.6.3.3 Reinforcement development may be inadequate due to corrosion, mechanical damage, insufficient or loss of concrete cover, delaminated concrete, concrete strength, or other conditions. Equations to calculate the development length have also changed over time and current equations may require longer development lengths than earlier equations. The design of the repair should evaluate the required development length. Detailing of the repair should include the proper development of new reinforcement to achieve the design force. ACI 318 provides development equations and requirements for detailing of steel reinforcement. ACI 369.1 (or ASCE/SEI 41) provides an equation when development length of existing reinforcement does not meet ACI 318. ACI 440.1R and ACI 440.2R provide detailing guidance for internal FRP reinforcement and externally bonded FRP reinforcement, respectively. Additional information can be found in fib Bulletin No. 10.

7.6.4 Prestressed structures

R7.6.4 Prestressed structures

R7.6.4.1 Requirements for repair of structures with bonded and unbonded prestressing are different. Post-tensioned structures (with bonded and unbonded tendons) are often cast-in-place monolithic structures, whereas pretensioned structures (with bonded strands) are often single-span precast structures. Each system is unique and should be individually considered. The repair of prestressed structures requires a condition assessment of the existing tendons. Repair of unbonded tendons may require tendon detensioning. Guidance for analysis, evaluation methods and repair techniques of unbonded post-tensioned structures is provided in ACI 423.4R, ACI 222.2R, ICRI Guideline No. 210.2, PTI DC80.2-10, and PTI DC 80.3/ICRI 320.6.

R7.6.4.2 Analysis to evaluate the effects of structural modifications should verify that strength is adequate and that all serviceability conditions (for example, deflection limits) are satisfied.

Analysis of prestressed structures is required to evaluate the effect of damaged or severed prestressing reinforcement on structural strength and performance. The effect of a severed bonded tendon is typically localized because the severed tendon is effective after a development length is achieved and the full strength of the tendon is reestablished. For structures with bonded tendons, shoring, if necessary, may only be required locally at the repair area.

Review of grouting quality assurance and supervision documents should be performed to evaluate grouted tendons in advance of any repair or rehabilitation of bonded post-tensioning systems. The presence of voids, moisture in ducts, chlorides and the extent of carbonation in the existing grout need to be identified. Methods for evaluation of chloride-ion content are listed in ASTM C1152M, ASTM C1218, and AASHTO T260. Field evaluation of grout may be required even if documentation of the original construction is available.
7.6.4.3 Stresses in remaining section after concrete removal during repair shall not exceed the limits established in the design-basis code.

R7.6.4.3 Removing surface concrete from a prestressed member may cause excessive compressive and tensile stress in the remaining concrete section and may alter secondary forces and moments due to prestressing in indeterminate structures. This condition is more critical for prestressed joists and girders that have a relatively small section and large prestressing force. Slabs are less critical due to the relatively small initial precompression. This change is acceptable as long as durability and strength are addressed as part of the repair design. The impact of removing concrete from a post-tensioned structure is addressed in Scollard and Bartlett (2004). PTI DC 80.3/ICRI 320.6 provides guidance for removing concrete around anchors and splices to prevent catastrophic anchorage failure.

7.6.5 Anchoring to concrete—Post-installed anchors shall be designed in accordance with ACI 318 to transfer design

R7.6.5 The design of post-installed anchors requires careful consideration of the loads to be resisted. Anchors

Unbonded tendons are designed to be permanently debonded from the member and often extend over multiple spans. As a result, damage or discontinuity of a tendon at one location will reduce the strength for the entire length of the tendon.

If unbonded tendons are severed, the prestressing force is assumed to be lost for the full length of the tendon. Releasing or cutting tendons may affect multiple spans and may require shoring beyond the area where cutting or releasing of tendons occurs. Adjacent spans may require temporary shoring depending on the number of tendons severed at one time and the applied loads. Analysis based on actual loading at the time of the modification may show shoring to be unnecessary.

Repair and structural modification may require detensioning of prestressing tendons. Unbonded tendons should be detensioned in a controlled manner to ensure performance and safety. Unless not needed based on analysis, unbonded tendons should be reanchored and restressed to restore required structural strength. Cut or damaged unbonded tendons can be restored by splicing or by installing new tendons with anchors at intermediate locations, at the end of the structural member or the edge of any new openings.

The stressing force in a repaired tendon depends on the condition and type of the repaired post-tensioned system and in certain cases this force can be less than the original force if determined to be acceptable by structural analysis. Further discussion of this topic can be found in PTI DC 80.3/ICRI 320.6.

Corrosion on prestressing strands for bonded and unbonded post-tensioned systems may have an effect on strand integrity and strength. Prestressing strands require examination for conditions such as corrosion pitting and hydrogen embrittlement (refer to ICRI Guideline No. 210.2 and ACI 222.2R).

If repairs to prestressed slabs or beams result in increased concrete tensile stress (that is, changing the classification of the prestressed flexural member as defined in ACI 318), impacts of the repair scheme on serviceability should be evaluated.
forces to the substrate considering possible anchor failure modes and the condition of the substrate into which the anchor is installed.

should have adequate strength to transfer design forces across all interfaces and into the existing member. All possible anchor failure modes should be considered to determine the design strength. Anchors should be selected considering the expected concrete substrate cracking condition. For example, post-installed anchors used in the tension zone of concrete members and in structures located in regions of moderate or high seismic hazard should be able to transfer the design seismic forces assuming a cracked concrete condition.

Design of post-installed anchors is provided in ACI 318, which includes provisions that require performance of post-installed anchors in both cracked and uncracked concrete. ACI 355.2 and 355.4 provide the standard required for qualifying post-installed anchors in cracked and uncracked concrete. Specifications for post-installed anchors should include installation, testing, and inspection procedures.

For post-installed expansion or undercut anchors, manufacturer’s installation instructions specify procedures for drilling, hole cleaning, installation, torque magnitude, and procedures to engage the anchor.

For adhesive anchors and dowels, hole cleaning and moisture conditions are critically important. Manufacturer’s printed installation instructions should specify procedures for drilling, hole cleaning, installation, and the care to be taken until the adhesive has cured.

Testing and inspection of post-installed anchors should be specified in the construction documents. Many building codes require that adhesive anchors be installed under special inspection procedures to ensure that the installation is correctly performed in accordance with the design and manufacturer’s procedure. Refer to ACI 318 for specific inspection requirements for post-installed anchors.

Repair shapes with sharp reentrant corners can cause stress concentrations that may result in cracking. Long, slender (high aspect ratio) repair areas also may result in transverse cracking. The shape of the repair should be considered to reduce stress concentrations and possible cracking. Methods discussed in ICRI Guideline No. 310.1R provide guidance to reduce cracking in concrete repairs including providing a uniform depth of edges and substrate, repair geometry, surface preparation, concrete removal below reinforcement (undercutting) and elimination of feather edge repairs.

Repairs to expansion joint materials are common, particularly those subjected to snow removal operations.

Design and selection of the expansion joints should consider the total anticipated movement of the expansion joint. Typically, expansion joint capacities listed in manufacturer’s literature are based on total movement from minimum installation width to maximum installation width and assume the joint will be installed when the joint is at the midpoint of this movement range. Joints installed in the summer or winter months will experience movement
7.7—Repair using supplemental post-tensioning

7.7.1 Supplemental post-tensioning shall be permitted for repair of structures.

7.7.2 The effects of the supplemental post-tensioning on the behavior of the structure shall be considered in the repair design.

7.7.2.1 Stresses due to supplemental post-tensioning shall be combined with existing stresses and the total shall not exceed the limits in the design-basis code.

7.7.2.2 Design of supplemental post-tensioning shall provide for the transfer of post-tensioning forces between the post-tensioning system and the structure. Design of concrete supplemental post-tensioning anchor zones shall be in accordance with ACI 318. Design of steel brackets and supplementary structural steel shall be in accordance with ANSI/AISC 360.

7.7.3 Provisions shall be made for effects of post-tensioning, temperature, and shrinkage on adjoining construction, including immediate and long-term deformations, deflections, changes in length, and rotations due to prestressing.

7.7.4 Post-tensioning losses shall be included in the design of supplemental post-tensioning systems.

7.7.5 Construction documents shall specify the repair sequence, including tendon placement, anchors, and stressing of the post-tensioned system.

R7.7—Repair using supplemental post-tensioning

R7.7.1 Supplemental post-tensioning can be applied to the structure externally, internally, or both.

R7.7.2 Supplemental post-tensioning can introduce moment, shear, and axial forces within the structure that should be considered in the design and detailing of the repair. The internal forces induced by the supplemental post-tensioning can be significant. For statically indeterminate structures, restraint to post-tensioning deformations can result in significant internal forces. Refer to ICRI Guideline No. 330.1 for selecting strengthening systems for concrete structures.

R7.7.2.1 Adding supplemental post-tensioning to a prestressed member may cause excessive compressive and tensile stress and may alter secondary forces and moments. External post-tensioning may result in changing the classification of prestressed flexural members as defined in ACI 318 Section 24.5.2. This change is acceptable as long as durability and strength are addressed as part of the repair design.

R7.7.2.2 Anchors for new post-tensioned reinforcement should be designed and detailed for the transfer of post-tensioning forces to the existing structure. Bearing, spalling, and bursting forces created at anchor zones should be considered. Strut-and-tie modeling, as given in ACI 318, may be used to design post-tensioning anchor zones.

R7.7.3 The post-tensioning forces may be restrained by adjacent stiff members such as walls, and reduce the effect of the prestressing on the intended member or have unintended effects on the adjacent construction.

R7.7.4 Losses include wedge seating in the anchor; elastic shortening; creep of original concrete; shrinkage of original concrete following installation of the supplemental prestressing; creep of repair material; shrinkage of repair material; prestressing relaxation; and friction and wobble between the post-tensioning reinforcement and ducts, bearings, or deviators. Assessment of losses of supplemental post-tensioning force should consider the existing conditions of the repaired elements, as the members may have already experienced time-dependent creep and shrinkage.

R7.7.5 Repair design using supplemental post-tensioning systems should include construction documents for installation sequence including shoring, removal of concrete, placement of new material and reinforcement, additional anchor requirements, horizontal shear transfer requirements, curing, and stressing. Installation of supplementary post-tensioning...
7.7.6 Structural members repaired or modified with externally installed unprotected post-tensioning shall have adequate unrepaired strength, in accordance with 5.5.

7.8 Repair using fiber-reinforced polymer (FRP) composites

7.8.1 Fiber-reinforced polymer composites in conformance with ACI 440.6 and ACI 440.8 shall be permitted to repair concrete structures.

R7.7.6 Unless protection of the post-tensioning strengthening system is provided to prevent sudden failure of the member in case the external post tensioning reinforcement is damaged or becomes ineffective (such as fire or impact), the structural member should have adequate strength without the post-tensioning reinforcement to support factored loads, as defined in Chapter 5.

R7.8—Repair using fiber-reinforced polymer (FRP) composites

R7.8.1 Fiber-reinforced polymer fabrics, bars, or shapes can be used as externally bonded reinforcement, internal reinforcement, and as internal or external prestressed reinforcement. FRP shapes may be used as additional stand-alone structural members. Design and detailing of externally bonded FRP systems should be consistent with ACI 440.2R. Particular attention should be given to strength increase limits, service limits, and determination of FRP material design properties.

Design and detailing of internal FRP reinforcement should be consistent with ACI 440.1R. Particular attention should be given to service limits and determination of FRP material design properties.

If internal prestressed FRP reinforcement is used, the design and detailing should be consistent with ACI 440.4R. FRP systems should only be installed in or on sound concrete. Concrete distress, deterioration, and corrosion of reinforcement should be evaluated and addressed before the application of the FRP system. Surface preparation requirements should be based on the intended application of the FRP system. FRP applications can be categorized as bond-critical or contact-critical. Bond-critical applications, such as flexural or shear strengthening of beams, slabs, columns, or walls, require an adhesive bond between the FRP system and the concrete. Contact-critical applications, such as confinement of columns, only require intimate contact between the FRP system and the concrete. Contact-critical applications do not require an adhesive bond between the FRP system and the concrete substrate, although one is often provided to facilitate installation. ACI 440.2R provides descriptions of FRP applications and surface preparation and repair requirements.

For bond-critical applications, the concrete substrate should possess the necessary strength to develop the design forces of the FRP system through bond. The substrate, including all bond surfaces between repaired areas and the original concrete, should have sufficient direct tensile and shear strength to transfer force between the existing substrate and FRP system. The tensile strength of the substrate should be at least 200 psi as determined by a pull-off type adhesion test per ASTM D7522/D7522M. Contact-critical applications are not required to meet this minimum bond value as
the design forces of the FRP are developed by deformation or dilation of the concrete section.

For bond-critical applications, the concrete surface should be prepared to a minimum concrete surface profile (CSP) 3 as defined by the ICRI Guideline No. 310.2R. In contact-critical applications, surface preparation should promote continuous intimate contact between the concrete surface and the FRP system. Surfaces to be wrapped should, at a minimum, be flat or convex to promote proper loading of the FRP system.

FRP systems should not be applied to damp or wet surfaces unless the epoxies are formulated by the manufacturer for such applications. Moisture content of the concrete substrate should be evaluated before application of the FRP system as it may inhibit bonding between the concrete substrate and epoxy polymer. Surface moisture should not exceed the limits established by the manufacturer. Testing for presence of moisture should be done in accordance with manufacturer’s written recommendations or one of the following: ASTM D4263 – “Standard Test Method for Indicating Moisture in Concrete by the Plastic Sheet Method;” AASHTO FRPS-1-UL – “Guide Specifications for Design of Bonded FRP Systems for Repair and Strengthening of Concrete Bridge Elements,” first edition; ACI 548.1R; ASTM F1869 – “Standard Test Method for Measuring Moisture Vapor Emission Rate (MVER) of Concrete Subfloor Using Anhydrous Calcium Chloride;” ASTM F2170 – “Standard Test Method for Determining Relative Humidity in Concrete Floor Slabs Using In Situ Probes;” or ASTM F2420 – “Standard Test Method for Determining Relative Humidity on the Surface of Concrete Floor Slabs Using Relative Humidity Probe Measurements and Insulated Hood.”

The surfaces to receive moisture testing and the testing equipment should be acclimated near the relative humidity levels and temperatures that the design is anticipated to have in service. Variation between testing and in-service conditions may provide inaccurate or misleading testing results.

7.8.2 Structural members repaired or modified with externally-applied FRP composites shall have adequate unrepaired strength, in accordance with 5.5.

7.9—Performance under fire and elevated temperatures

7.9.1 Design of the repair system shall consider elevated temperature performance and shall comply with the fire resistance ratings of the structural members and other fire safety requirements in accordance with the design-basis code.

7.9—Performance under fire and elevated temperatures

R7.9—Performance under fire and elevated temperatures

R7.9.1 Regardless of the repair system used, performance of the repaired element under fire and elevated temperatures should be evaluated and the system should be detailed and materials selected to provide adequate performance. The repaired elements should comply with applicable building code requirements and relevant fire regulations valid at the project location. Structures renovated for different use or strengthened to support higher loads may require a more stringent fire rating than the original structure. Other requirements such as flame spread and smoke density should also be considered in accordance with the general existing building code and ASTM E84.
7.9.2 It shall be permitted to design a repair without supplemental fire protection if the un repaired member has adequate strength during a fire event considering the reduced material properties due to fire exposure in accordance with 5.5.3.

7.9.3 The properties of the specified repair materials at elevated temperatures shall be considered.

7.9.4 Repairs using adhesives shall consider their performance at elevated temperatures.

7.9.5 Supplemental fire protection to improve the fire rating of repaired systems shall be permitted.

7.9.6 Fire rating of repaired systems, based on ACI 216.1, shall be permitted.
the use of reduced material strength due to fire exposure and a strength reduction factor during fire of 1.0.

The criteria for evaluating a structure for fire safety are different than those for strength design and typically incorporate lower material strengths and required strength, and may not require the use of strength reduction factors (refer to Section 5.5.3). The licensed design professional should verify that the fire-reduced strength of the member exceeds the force demand due to expected service loads during the fire event. The fire-reduced strength should be based on reduced material strengths for the maximum expected temperature in a fire event, which can be determined in accordance with ASTM E119 and ACI 216.1.

Section 1.2 of ACI 216.1 allows alternative methods to assess the fire resistance of assemblies. The fire reduced strength as well as the effect of fire protection system on the overall performance and fire rating of an existing and repaired element can also be determined utilizing available design models and finite element numerical procedures. Descriptions of the detailed analytical methods can be found in Buchanan (2001) and Technical Report 68 (2008) by the Concrete Society.

The fire resistance or rating of a repaired system or assembly can be determined through full scale testing in accordance with ASTM E119, which requires the application of the expected service load to the test specimen during the full-scale fire test.
8.1—General

8.1.1 Durability of individual repairs, the repaired structure, and the interaction between the repaired areas and the remaining structure shall be considered.

R8.1—General

R8.1.1 The durability of materials incorporated into a repair depends on the ability of the materials to withstand the environment where they are installed. A repaired section is considered to be the combination of the installed repair material(s) and the substrate material(s). The durability of repairs is dependent on the compatibility between repair materials, the structure, and the surrounding environment. To achieve compatibility, the repair and structure need to interact on several levels without detriment, including chemical, electrochemical, and physical behavior.

For repair durability design, the design service life is the time frame for which durability should be considered. The design service life requirements for a repaired structure are established by the licensed design professional in consultation with the Owner to achieve a repair that satisfies project requirements including strength, safety and serviceability. Such design service life should be reflected in the repair design and maintenance requirements, as well as incorporated into the construction documents. Design service life may be achieved through satisfactory repair construction practices, including the material selection, surface preparation and application of the repair materials. The design service life of the structure and repaired members, including maintenance requirements, may be estimated by considering the durability of the repair materials and their interaction with the structure. Service life and the parameters to be considered, the limitations, and methods available for conducting a service life prediction are presented in ACI 365.1R. Some examples of end of service life where durability parameters are not met include:

(a) Unacceptable reduction in structural performance
(b) Unacceptable frequency of maintenance cycles and associated activities
(c) Exceeding maximum crack width or crack frequency from corrosion, shear, torsion, flexure
(d) Exceeding maximum permissible chloride level at the interface of the steel in the repair area, or in adjacent areas
(e) Depth of carbonation leading to corrosion of reinforcement
(f) Unacceptable reinforcement section loss due to corrosion
(g) Exceeding maximum concrete deterioration level, mass loss or unacceptable surface conditions due to deterioration mechanisms, such as corrosion, freeze-thaw, chemical attack, abrasion, sulfate attack, alkali-silica reaction (ACI 221.1R, ACI 364.11T), or delayed ettringite formation
(h) Loss of watertightness or excessive/unacceptable leakage

8.1.2 Cause(s) of current conditions, defects, and potential future deterioration of repairs shall be assessed as part of the repair design.

R8.1.2 The presence of deterioration and its cause(s) should be determined as a first step in repair durability design. Causes of deterioration include:
8.1.3 Repair materials and methods shall be selected to be compatible with the structure, and within the service environment. Anticipated maintenance shall be considered in the selection of repair materials and methods.

R8.1.3 Compatibility in concrete repair systems can be defined as the balance of physical, chemical and electrochemical properties, as well as volume changes between the repair, the reinforcement, and the existing substrate. This balance ensures that the composite repair system withstands stresses induced by loads, chemical and electrochemical effects, and restrained volume changes without distress and deterioration over a designed period of time (Vaysburd and Emmons 2006).

Repaired sections should be resistant to expected service conditions that can result in deterioration during the design service life, including the causes of deterioration listed previously, and combinations of these causes.

Repaired sections should be resistant to:
(a) The ingress of chlorides and other corrosive contaminants that are present in the remaining concrete or the ingress of corrosive contaminants into the concrete that lead to corrosion of reinforcement or other embedments (8.4).
(b) The effects of thermal exposure and cycles.
(c) Freezing-and-thawing damage if critically saturated and subject to a freezing-and-thawing environment.
(d) Scaling if exposed to salts.
(e) Deterioration due to exposure to ultraviolet or other radiation deterioration within the repair environment unless other means are provided to address such deterioration.
(f) Fatigue deterioration resulting from loading cycles and load reversal. For example, fatigue resistance may be needed in repair areas subject to many cycles of repeated loading.
(g) Impact, erosion, and vibration effects if exposed to conditions causing deterioration by these mechanisms.
(h) Abrasion due to heavy traffic, impingement of abrasive particles, or similar conditions.
(i) Chemical deterioration which may result from sulfate attack, acids, alkalis, solvents, leaching of cementitious materials due to soft water, salt crystallization, and other factors that are known to attack or deteriorate the repair material or concrete substrate. Water penetration into concrete is associated with many types of chemical attack and other deterioration mechanisms.
(j) Carbonation-induced corrosion. Carbonation of concrete and repair materials reduces their pH and dimin-
8.2—Cover

8.2.1 Concrete cover shall be in accordance with the design-basis code, or an equivalent cover shall be used. An equivalent cover using alternative materials and methods shall be approved in accordance with 1.4.2.

8.2.2 Concrete cover over remaining and new reinforcement shall meet minimum requirements to provide sufficient (i) corrosion protection; (ii) fire protection; and (iii) anchorage and development.

8.2.3 Deterioration resulting from deleterious aggregate, alkali-aggregate reactions or other aggregate durability concerns.

8.2.4 Deterioration due to trapped moisture as a result of differential permeability between the repair and existing concrete, leading to freezing-and-thawing damage of critically saturated concrete, corrosion of embedded steel reinforcement, alkali-aggregate reaction, or sulfate attack of either the repair concrete or existing concrete.

Appropriate materials selection for concrete repair is discussed in ACI 546.3R.

Environmental classes that may affect durability performance are shown in Table R8.1.3.

$^1$Percent sulfate by mass in soil shall be determined by ASTM C1580.

$^2$Concentration of dissolved sulfates in water, in ppm, shall be determined by ASTM D516 or ASTM D4130.
8.3—Cracks
8.3.1 The cause(s) of cracks shall be assessed, and mitigation of cracking shall be considered in the repair design. As part of a repair design, cracking mitigation methods shall consider the causes, movement, size, orientation, width, and pattern of cracks. The characteristics of the substrate, location, and evidence of water transmission shall be determined to assess the appropriate method of repair. Active water infiltration shall be corrected as required for the durability of the structure.

8.3.2 The design of repairs shall consider the effects of cracks on the expected durability, performance, and design service life of the repair and structure as a whole.

R8.3—Cracks
R8.3.1 Cracks can reduce the protection provided by the effective cover over steel reinforcement and lead to water and deleterious material ingress, which accelerates the deterioration of embedded reinforcement and can cause other concrete deterioration issues such as freezing-and-thawing deterioration, alkali-aggregate deterioration, and chemical attack. Identification of their cause(s) and evaluation of their impact on a structure or a concrete component is described in ACI 224.1R. Guidance for the assessment of cracking caused by earthquakes is provided in FEMA 306.

R8.3.2 Not all cracks need to be repaired, however, all cracks have the potential to become active cracks. Cracks in concrete structures can be detrimental to the long-term performance of a structure if the cracks are of sufficient size to allow for the ingress of deleterious materials into the structure, and guidance for critical crack sizes is provided in ACI 224R, Table 4.1. Consideration should be given to post-repair cracking and the need for protection of the existing concrete and repair material from the ingress of deleterious materials. ACI 224.1R provides guidance for the prevention and control of cracks.

There are a variety of different materials that have been used for crack repair, and the correct specification for a given application will affect the design service life of the repair. For cracks that are essentially acting as a joint or are active, one type of effective repair is to seal the crack with an elastomeric sealant at the concrete surface(s). Crack injection can be another effective repair approach. For repair by crack injection, the process and material should be appropriate to the site conditions. Dormant cracks can be repaired by injection using materials such as epoxy, polyurethane, latex in a cement matrix, microfine cement, and polymethacrylate. Crack injection should not be used to repair cracks caused by corrosion of steel reinforcement and alkali aggregate reaction unless supplemental means are employed to mitigate the cause of the cracks.
8.4—Corrosion and deterioration of reinforcement and metallic embedments

8.4.1 The corrosion and deterioration of reinforcement and embedded components shall be considered in the durability design. Repairs shall not contain intentionally-added constituents that are corrosive to reinforcement within the repair area.

8.4.2 The impact on the design service life of the repaired structure shall be considered if it is anticipated that corrosion products cannot be removed from the reinforcement during repair.

8.4.3 The quality of existing concrete and its ability to protect reinforcement from corrosion, fire and other forms of damage and deterioration shall be considered.

8.4.4 Galvanic corrosion between electrochemically dissimilar materials shall be considered.

R8.4—Corrosion and deterioration of reinforcement and metallic embedments

R8.4.1 Untreated reinforcement corrosion limits the life expectancy of repair areas, repair materials, and repaired structures. ICRI No. 310.1R provides guidelines on removal of damaged concrete and cleaning of reinforcement. Repairs that do not address reinforcement corrosion may negatively impact the design service life and require more intensive monitoring. The structural design considerations for corroding reinforcement on repairs are described in 7.6.3.1.

R8.4.2 Ideally corrosion products should be removed from reinforcement in repairs. In some situations, due to congestion of reinforcement, access limitations, load considerations, or other factors, it is not possible to remove corrosion products from the steel reinforcement. Situations exist where corroding reinforcement that cannot be adequately cleaned or repaired will remain in the repaired structure. The effects of uncleaned reinforcement on the long-term durability of the repaired structure should be considered in these situations. Supplemental corrosion mitigation strategies may be needed in these situations.

R8.4.3 Water and chemical penetration into the concrete can cause corrosion of metallic embedments and damage to nonmetallic reinforcement.

The corrosion of embedded metals adjacent to the repair may be accelerated due to differing electrical potential between electrically continuous reinforcement in the repair area and external to the repair area. This form of corrosion is commonly referred to as the “anodic ring” or “halo effect,” and is discussed in ACI 364.3T, ACI 546R, and “ACI RAP Bulletin 8” (ACI Committee E706 2005). The rate of anodic ring corrosion depends upon the chloride content, internal relative humidity, and temperature.

The anodic ring effect, which may be induced by certain repairs, should be addressed by incorporating appropriate corrosion mitigation strategies such as cathodic protection or corrosion inhibitors. ACI 222R, ACI 222.3R, ACI 364.3T, ACI 546R, and Technical Report 50 (The Concrete Society 1997) and FAQ sections from Concrete International (2002a,b,c) provide guidance for corrosion prevention, mitigation and inhibition. Both carbonation and chloride contamination may require consideration and are discussed in ACI 546R.

Aesthetics may be affected by different means of protection and may also require consideration. Damage due to fire and fire protection requirements are discussed in 7.9.

R8.4.4 Reinforcement or metallic embedments in the repair area with differing electrochemical potentials, environments, or both, should be isolated from the existing reinforcement, or the existing reinforcement and metal embedments should be protected to minimize galvanic corrosion. For example, rail or post-pocket repairs that use dissimilar...
8.4.5 Corrosion protection of bonded and unbonded prestressing materials and prestressing system components shall be addressed during the repair design.

8.4.6 If electrochemical protection systems are used to protect steel reinforcement in repair areas and structures, the interaction of the protection system with the repaired elements, the entire structure, and environment shall be considered.

8.4.7 Repair materials and reinforcement shall be selected and detailed to be compatible such that the characteristics of each material do not adversely affect the durability of the other materials or of the existing concrete and reinforcement.

CODE

R8.4.5 The presence of prestressing force in the steel and the need to transfer the prestressing force into the concrete makes corrosion damage in prestressed concrete members more critical than traditionally reinforced structures (refer to ACI 423.4R). Section 7.6.4 addresses the structural requirements for the repair.

The bonded or unbonded nature of the prestressing steel, the condition of the steel at the repair area, the attachment of the steel to the structure, the as-designed corrosion protection measures, the existing corrosion condition, the prestressing steel sheathing type and its risk for gaps and breaches that provide transmission pathways for contaminants, and the continuity of the prestressing steel need to be considered to address corrosion protection of the structure. Refer to PTI DC80.3-12/ICRI 320.6 and ACI 222.2R.

Hydrodemolition and other types of material removal methods should be used cautiously if the structure contains unbonded prestressing steel reinforcement. In these situations, water can be introduced into the sheathing surrounding the steel (refer to ICRI No. 310.3), affecting the long-term durability of the prestressing steel reinforcement.

R8.4.6 Structures using impressed current electrochemical protection or mitigation systems should have continuous reinforcement, separate zones, or provisions should be made to make the steel electrically continuous. Impressed current electrochemical protection systems should be designed and maintained to not promote an alkali-aggregate reaction (AAR) and to avoid embrittlement of prestressing steel.

Impressed current electrochemical protection systems should include a monitoring and maintenance plan developed by a licensed design professional specializing in the design of corrosion protection systems (refer to NACE 01101, NACE 01102, NACE 01104, NACE 01105, NACE SP0107, NACE SP0290, and NACE SP0390).

R8.4.7 Incompatibilities can arise from the use of inappropriate materials or components, or dissimilar electrochemical characteristics or physical properties, which can negatively impact the concrete and reinforcement. Some examples include:

(a) In certain situations such as exposure to high temperatures, polyvinyl chloride (PVC) and other polymer-based materials can deteriorate, releasing decomposition products found to cause corrosion.

(b) Even if the conventional steel reinforcement becomes more noble in electrical contact with a dissimilar metal (for example, embedded aluminum conduit in the presence of chlorides), considerable concrete damage can arise (Monfore and Ost 1965).

(c) Fiber-reinforced polymer (FRP) wrapping should not be used as a corrosion repair strategy on members experiencing corrosion of embedded reinforcement, unless the concrete is
8.5—Surface treatments and coatings

8.5.1 Moisture transmission through the structure and the influence of the surface treatment on the durability of the structure shall be considered.

8.5.2 The selection of surface treatments applied to concrete surfaces shall consider the impact of abrasion, concrete cracks and their anticipated expansion and contraction, and anticipated movement of the structure on the repair system durability, the surface treatment, and the anticipated design service life of the structure.

R8.5—Surface treatments and coatings

R8.5.1 Surface treatments, coatings, sealers, or membranes are commonly used to limit the ingress of deleterious materials and moisture into the structure to reduce future deterioration of the structure. Surface treatments, coatings, sealers, and membranes may have a shorter service life than the concrete and can be considered as consumable or requiring periodic replacement or repair to maintain effective protection of the concrete (ACI 515.1R).

In some situations, encapsulation of moisture and deleterious materials by a surface treatment has been found to cause or accelerate deterioration. The condition of the concrete should be appropriate to receive a specific surface treatment, coating, or membrane (ICRI No. 310.2R).

R8.5.2 Crack development and propagation provide an accelerated mechanism for ingress of moisture and deleterious materials and may also cause a surface treatment to become ineffective.
CHAPTER 9—CONSTRUCTION

9.1—General

Construction documents shall specify that:

(a) The contractor has the responsibility to construct the project in accordance with the construction documents and with appropriate standards.

(b) The contractor has the responsibility to provide the necessary resources and access for inspection, testing, field observations, and quality control of the work.

(c) Specific temporary shoring and bracing requirements in accordance with Section 9.2.

(d) Specific jacking requirements.

(e) Project-specific inspection, testing, and construction observation requirements of Chapter 10.

9.2—Stability and temporary shoring requirements

9.2.1 Construction documents shall specify:

(a) Portions of the work that require temporary shoring and bracing during the period before the repair implementation for safety purposes and during construction

(b) Design loads and necessary spacing limitations for design of temporary shoring and bracing

(c) Contractor responsibilities to install, provide quality control, and properly maintain the temporary shoring and bracing

9.2.2 Temporary shoring and bracing design shall consider:

(a) Accommodation for in-place conditions and changes in conditions over the period of the repair phases, per 9.2.7

(b) Effects from measured lateral and vertical displacements, tilting or listing, secondary effects, and superimposed loads

(c) Impact of the temporary shoring and bracing on the structure

(d) Effects of deformation compatibility of the shoring system with the supported and supporting structural members and systems, in accordance with 9.2.6

(e) Structural stability of members, systems, and the structure in accordance with 9.2.5 and 9.2.6

(f) Effects of damage or deterioration of existing members and systems in accordance with 9.2.8

9.2.3 Shoring and bracing design shall be performed by a licensed design professional.

R9—CONSTRUCTION

R9.1—General

The information to be presented in construction documents is described in 1.6.1. Specific to the construction process, the construction documents should indicate that the contractor is responsible for construction consistent with the project plans and specifications, and convey project specific shoring, bracing and jacking requirements. During the work, the contractor should make the work available for inspection and observations by the licensed design professional, repair inspectors, and other quality assurance personnel.

R9.2—Stability and temporary shoring requirements

R9.2.1 Project-specific design criteria for the temporary shoring and bracing in the construction documents should include requirements for loading, displacement limits, spacing, placement, and quality control during construction. ACI 563 provides specifications for shoring of repairs.

R9.2.2 Temporary shoring and bracing members should be designed to consider changes in bracing and shoring conditions during repair construction and as required to support construction operations. Design of temporary shoring and bracing members should be based on the in-place loads on the structure, deformations of the structure, and anticipated superimposed loads during construction. Secondary effects that may need to be examined in shoring and bracing design include geometric and material nonlinear response, member and foundation displacement, and internal member forces developed due to placement and alignment of shoring and bracing elements.

Anticipated loads, such as snow, seismic, wind, and construction and occupancy live loads, should be considered in the design criteria of the temporary shoring and bracing. Design requirements for shoring are contained in ASCE/SEI 37. Shoring design guidelines are contained in AISC Steel Design Guide Series 10 (Fisher and West 2003) and ACI SP-4.

R9.2.3 Shoring and bracing design is not usually performed by the licensed design professional of record for the repair design. The contractor will usually retain a specialty engineer to prepare the temporary shoring design details and shoring-plans, showing loads, member type, spacing, and placement sequence for temporary shores and braces at the phases of planned repairs.
9.2.4 The licensed design professional for the repair design shall review temporary shoring and bracing design and details for compliance with the requirements of the project repair design and the temporary shoring and bracing criteria.

R9.2.4 Temporary shoring and bracing design and installation details should be reviewed by the licensed design professional for the repair project to assess the impact of the shoring on the structure, and to verify conformance of the proposed shoring with project-specific requirements. Refer to 5.1.4 for load requirements associated with shoring and temporary construction. Review of the shoring design by the licensed design professional for the repair design does not normally include a comprehensive review of the shoring design prepared by the specialty engineer and should not be considered a validation of the specialty engineer’s design.

9.2.5 The shoring and bracing shall maintain the global structural stability of the structure before remedial construction and during the repair phases.

R9.2.5 The assessment of global structural stability includes the overall structure, members and systems affected by repair, and temporary lateral bracing elements that contribute to overall stability. Stability of these elements should be considered during the phases of the repair process. Temporary measures may be needed to provide lateral bracing and shoring of affected members and systems. If necessary, the criteria to temporarily preload members should be included in the construction documents. Review and redesign for variations in the construction proposed by the contractor with changes in temporary shoring and bracing design and detailing should be addressed in the construction documents.

The licensed design professional should be aware that compression-controlled columns with high axial loads in a structure with substantial structural damage may behave in a brittle manner, with little warning prior to localized failure or possible progressive collapse. Therefore, caution should be taken in the design and installation sequence for stabilization measures in these situations.

9.2.6 The shoring and temporary bracing shall maintain the structural stability of members and systems before construction and during the repair phases.

The lateral forces for temporary bracing design shall be determined using generally accepted engineering principles or as required by the design-basis code. Temporary shoring and bracing shall be designed to provide sufficient stiffness to prevent vertical and lateral displacement of the shored or braced members in excess of limits specified by the licensed design professional for the repair in the construction documents.

R9.2.6 Supplemental bracing for compression members may be required if the cross section or unbraced length of a compression member is modified during the repair process. Compression members include columns, walls, beam flanges, and other members, such as chords or diaphragms that resist compressive loads. The design of bracing members is described in various publications (AISC 2006; ANSI/AF&PA NDS 2014). The design load for a bracing member should be based on the existing dead and live loads, construction loads, and other loads that may be resisted by the compression member. A lateral force of 2 percent of the axial load in the member being braced is commonly used as a minimum load in the design of bracing members (ANSI/AISC 360-10).

9.2.7 The design of shoring and bracing members shall accommodate in-place conditions and changes in conditions during construction. The design shall, at a minimum, include consideration of (a) the changes in load paths, (b) construction loads, (c) unbraced lengths, and (d) the redistribution of loads and internal forces that result from removal of existing adjacent framing or changes in applied loads on structural members.

R9.2.7 Removal of column, beam, wall, and floor slab elements or parts thereof during repair construction and the placement of shoring and bracing can result in the redistribution of loads and internal forces within the building structure. The removal of framing members, diaphragms, or slabs can also affect the unbraced length of the framing members in the removal area. Effects of the removal of elements should be considered in assessing the structure and shoring and bracing design.
9.2.8 Where structural members are required to support the structure and superimposed loads before repair and during construction, the structural capacity of damaged or deteriorated members shall be evaluated. The evaluation shall consider the actual cross section of the member and reinforcing at the time of the repair including losses of capacity due to damage and deterioration. Structural members that require temporary shoring and bracing to be installed and maintained in place during construction until the member is repaired shall be identified on the construction drawings.

R9.2.8 Design of shoring and bracing members and the evaluation of members should be based on the member cross sections before and during the time of repair implementation. To account for unknown conditions, the evaluation by the licensed design professional should consider the importance of the member to the overall stability of the structure.

9.3—Temporary conditions
9.3.1 Load and load factors used during the assessment and construction processes shall be in accordance with 5.1.4.

R9.3—Temporary conditions
R9.3.1 During the assessment and repair process, a temporary reduction in design load may be allowed, except if prohibited by authorities having jurisdiction or local building codes. Reduction in the design load intensity should be determined using the in-place condition of the structure and the time required for the completion of stabilization measures or repairs. ASCE/SEI 37 provides information on reductions in loads based upon the duration of a project. If a change in the length of the project or a delay occurs, the reduced design loads may no longer be appropriate.

9.4—Environmental issues
9.4.1 Construction documents shall specify the contractor or other designated party is responsible for implementing environmental remediation measures, reporting new conditions encountered, and controlling construction debris, including environmentally hazardous materials and conditions.

R9.4—Environmental issues
R9.4.1 Assessment and repair of a structure can result in the exposure of workers and the public to potentially hazardous materials and conditions. Hazardous materials may be exposed, dislodged, carried into the air, or discharged as effluent into surface drainage during the assessment and repair process. Hazardous conditions include noise, nuisance dust, misdirected drainage, and falling debris. The Owner should have an environmental assessment performed during the structural assessment and repair process in the areas to be repaired before any work to identify hazardous materials with the potential to present health issues to the workers and public, unless the Owner can attest that the structure is free of hazardous materials.

During the repair project, the contractor normally is responsible for the implementation of repairs and, accordingly, the control of construction debris, dust, and other materials. Any new conditions uncovered during the repair process should be reported to the Owner and licensed design professional.
CHAPTER 10—QUALITY ASSURANCE

10.1—General
10.1.1 Quality assurance requirements of this chapter supplement the current and existing-building code provisions and shall be used for repair and rehabilitation construction.

10.2—Inspection
10.2.1 Concrete repair and rehabilitation construction shall be inspected as required by the building code and construction documents.

10.2.2 The construction documents shall include testing and inspection requirements applicable to the project.
the licensed design professional, or a combination of repair inspectors and the licensed design professional. Responsibilities for performing the inspections should be clearly delineated at the start of a project.

Repair inspector qualifications for inspection of concrete repairs should be demonstrated by certification or previous work history and as required by the authority having jurisdiction before being retained. An individual who has been certified as an ICRI Concrete Surface Repair Testing Technician (ICRI CRST) or as an ACI Construction Inspector (ACI C630) are examples of qualified inspectors. The licensed design professional may provide inspection services.

Inspection of concrete repair construction as specified in the construction documents should include review of the work in the field, review of construction documents, comparison of the work with construction documents, documentation and report of the work inspected as conforming or nonconforming, and whether corrections were made and verified or are still needed. Inspection and testing of post-installed anchor installation should be performed as required by the construction documents and in accordance with Chapters 17 and 26 of ACI 318-14.

Repair inspections should determine compliance with the intent of the contract documents, document the inspection, and report the inspection results. If the inspection shows conformance with the contract documents and no corrections are necessary, then the inspected work should be documented as conforming and reported to the licensed design professional and contractor, noting no corrections. If the inspection shows readily correctable issues and the issues are corrected by the contractor, then the inspected work should be documented as conforming and reported to the licensed design professional, Owner, and contractor with corrections noted and verified as completed. Nonconforming or deficient components, processes, and procedures including the parts of the repairs not passing inspection should be reported to the licensed design professional for review. Actions should be made to correct the process before resuming the repair construction and inspection process. Nonconforming repair construction may include:

(a) Existing construction that differs from the repair documents
(b) Deterioration, distress, or levels of distress beyond those anticipated in the design of repairs
(c) Deficiencies in repair components
(d) Deficiencies in construction processes and procedures

Material data sheets indicate the manufacturer’s stated material properties that should satisfy the required properties of each specific repair. The manufacturing date and shelf life of the repair material provide information that the material is within the manufacturer’s recommended time limits for installation.

Existing conditions describe the nature and extent of damage or deterioration, and size and condition of the members. Those conditions need to be verified for confor-
### Code Requirements for Assessment, Repair, and Rehabilitation of Existing Concrete Structures (ACI 562-19)

#### Section 10.2.3

The construction documents shall establish inspection requirements of existing conditions and reinforcement that need to occur before concealing with materials that obscure visual inspection.

#### Section 10.3—Testing of Repair Materials

10.3.1 Repair material tests and test frequencies shall be specified in the construction documents. Results of tests shall be reported as required by the construction documents and the design-basis code. Test records shall be retained by the testing agency as required by the design-basis code.

#### Commentary

- **R10.2.3** Removal of deteriorated concrete and reinforcement often uncovers unanticipated conditions that should be examined. Visual inspection and verification of existing conditions may require review of project-specific conditions before continuing the construction process and thus require pauses in the construction processes so as not to conceal components of the work before completing necessary inspections and verifications. If unanticipated conditions are identified by the repair inspector, the licensed design professional should be informed. The licensed design professional should examine these conditions and determine what measures are to be implemented before placement of new repair materials. The construction documents should specify the locations where inspection is necessary before concealment and provide for possible changes in these locations due to unforeseen conditions. In some projects, all locations will not need to be inspected and representative locations will provide suitable inspection.

- **R10.3—Testing of Repair Materials**

  R10.3.1 Tests of repair materials should comply with testing and test frequency of new concrete construction, unless otherwise specified in the contract documents and approved by the authority having jurisdiction. It is generally not practical to verify all manufacturers’ listed properties of proprietary materials, such as shrinkage, compressive and tensile creep, thermal expansion coefficient, and modulus of elasticity. In such cases, the licensed design professional should seek independent testing data from the manufacturer or others to verify specific manufacturer’s listed properties that are critical to the application for the specific lots (or batches) of material to be used. The licensed design professional should evaluate the data and, if necessary, have manufacturers perform testing to confirm that their material achieves the published values that they provided for the project. Refer to ACI 546.3R and ICRI No. 320.2R for guidance. Tests of repair materials’ bond to existing materials should comply with requirements of the contract documents.
Concrete repair materials testing personnel should be qualified by demonstrating competence to the satisfaction of the licensed design professional and building code official for testing types required of concrete repair and rehabilitation work.

As a minimum level of record keeping, the testing agency should maintain a record of the tests performed and the results consistent with the requirements for records in ASTM E329.

RA—CRITERIA AS A STAND-ALONE CODE

A.1—General

A.1.1 This Appendix shall apply if a jurisdiction has adopted this code including this Appendix by reference, but has not been adopted by the IEBC. When this Appendix is used, Chapter 4 shall not apply.

A.2—Design-basis code criteria

A.2.1 Unless prohibited by the authority having jurisdiction, the design-basis code criteria of the project shall be based on requirements set forth in this Appendix.

A.2.2 The design-basis code criteria of the project shall be determined based upon the results of the preliminary assessment (1.7) and the detailed assessment (Chapter 6), if performed, using the requirements set forth in this Appendix. The design-basis code criteria shall be used consistently for all assessment and repair, rehabilitation, and retrofit design in the work area or areas of the structure, excluding other options.

A.2.2.1 It shall be permitted to use the current building code in lieu of the original building code as the design-basis code for all damage states, deterioration, and faulty construction.

A.2.3 It shall be permitted to use this Appendix to determine the work category as shown in Table A.2.3.

RA.2—Design-basis code criteria

RA.2.1 The design-basis code criteria of the project shall be determined based upon the results of the preliminary assessment (1.7) and the detailed assessment (Chapter 6), if performed, using the requirements set forth in this Appendix. The design-basis code criteria shall be used consistently for all assessment and repair, rehabilitation, and retrofit design in the work area or areas of the structure, excluding other options.

RA.2.2 Structures constructed under previously adopted codes or before the adoption of a building code may not satisfy all current building code requirements. This Appendix contains specific requirements that determine if existing structures should be repaired, rehabilitated, or retrofitted to satisfy the requirements of the original or the current building code as the design-basis code. Local ordinances may also require that a structure be rehabilitated to satisfy the current codes. Throughout an existing structure, the design-basis code should not change. These requirements should be reviewed at the start of a project.

In the absence of mandatory local ordinances, the licensed design professional should determine if assessment of seismic resistance and repairs or strengthening retrofits of the member, system, or structure of the work area in an existing concrete structure are necessary using this Appendix. Section A.3.3 provides minimum assessment criteria for potentially hazardous seismic conditions. Provisions of ASCE/SEI 41 may not be applicable to nonbuilding structures being assessed.

RA.2.2.1 Most current building codes, such as those based on the IBC, provide acceptable safety based on consistent statistical probabilities. When using the current building code the resulting demand/capacity ratios provide the limits that should not be exceeded if assessing and designing remedial construction. Refer to Section R1.2.4.3.1 for additional commentary on the use of current building code as the design-basis code.

RA.2.3 Unless the local jurisdiction provides more restrictive requirements, this Appendix should be used to determine the assessment and design-basis criteria for the work categories of A.3 through A.9 and as summarized in Table A.2.3.
A.2.4 This code shall be used to assess and design repairs in the work area of existing structures. The current building code shall be used to detail new concrete members and connections between new concrete members and existing construction. When the original building code is used as the design-basis criteria for repairs, new concrete or reinforcing members built integrally with the existing concrete structure shall be designed using the original building code. Alternately, the new members shall be designed using the current building code.

A.2.5 In design of repairs to existing structures, detailing of the existing reinforcement within the work area need not comply with the current building code when using the original building code, if both of the following conditions are satisfied:

(a) The damage or deterioration to the existing reinforcement is addressed

(b) The repaired work area of the structure has capacity equal to or greater than demand per 5.2.2 using the original building code requirements or satisfies the requirements of A.5.3 when using allowable stress design

RA.2.5 The licensed design professional should review the development of existing reinforcing steel, when cracking damage is evident near the ends of the reinforcement to determine if the cracking is indicative of potential development failure beyond the restrictions of this section. Research has shown that development length equations from previous versions of ACI 318 may be unconservative for top reinforcing steel bars (Feldman and Cairns 2017). Significant changes have occurred in the building code requirements increasing development length of reinforcing steel.

When the basis of design is the current building code, the licensed design professional should consider the following:

(a) Assessing demand/capacity ratios for the existing reinforcing steel with current development length provisions

(b) Confinement details of the reinforcement when assessing seismic resistance

The licensed design professional should determine if structural behavior indicates adequate performance. ACI
A.3—Potentially dangerous structural conditions

A.3.1 A structural assessment shall be performed in the work area to determine if potentially dangerous structural conditions are present, when there is a reason for the licensed design professional to question the capacity of the structure or when potentially dangerous structural conditions are observed as a part of the preliminary assessment.

A.3.1.1 Potentially dangerous structural conditions shall be reported in accordance with 1.5.2.

A.3.2 For gravity, fluid, soil, and wind loads, potentially dangerous structural conditions exist in members or structures where the demand/capacity ratio is greater than 1.5 as shown in Eq. (A.3.2).

\[ \frac{U_c}{\phi R_{cn}} > 1.5 \]  \hspace{1cm} (A.3.2)

In Eq. (A.3.2), \( U_c \) is the strength design demand determined by using the nominal gravity, fluid, soil, and wind loads identified in the current building code and the factored load combinations of ASCE/SEI 7, excluding seismic forces; and \( \phi R_{cn} \) is the capacity adjusted by the strength reduction factor (\( \phi \)) in Section 5.3 or 5.4 of this code.

A.3.2.1 If the demand/capacity ratio exceeds 1.5 for the work areas, the design-basis criteria shall be the current building code.

A.3.2.2 For structure with no risk of collapse under service load conditions, Sections A.4 through A.9 shall be used to determine the design-basis criteria.

RA.3—Potentially dangerous structural conditions

RA.3.1 Structural assessments are required when damage, deterioration, structural deficiencies or behavior are observed during the preliminary assessment that are unexpected or inconsistent with available construction documents. The structural condition assessment should be performed in accordance with 1.7 or Chapter 6, or both. The commentary to 1.7.4 has information on means and methods to determine if there is a reason to question the capacity of the structure. Results of the condition assessment should also be reviewed to identify if potentially dangerous conditions are present. Potentially dangerous structural conditions include any instability, the potential for collapse of overhead components or pieces (falling hazards), or a significant risk of collapse exists under service load conditions.

RA.3.2 Demand/capacity ratios are used to quantify the adequacy of the member or structure. The threshold demand/capacity ratios determine when different levels of intervention may be required. For each demand/capacity ratio, this code provides direction on how the demand and capacity are determined. Demands may be determined based upon loads associated with current building codes (\( U_c \) as defined above) or loads specified during the original design (\( U_o \) as defined in Section 4.5.1) of the structure. The calculated capacity of the structure will vary depending upon the condition of the structure and extent of evaluation used to confirm as-built properties of the structure.

In assessing potentially dangerous structural conditions the strength design demand of Eq. (A.3.2.2) combines current building code nominal gravity loads (dead, live, and snow) with lateral loads from fluid, soil and wind (excluding seismic forces) using factored load combinations of ASCE/SEI 7. A demand/capacity ratio greater than 1.5, calculated using Equation (A.3.2.2), represents a condition with limited to no margin of safety against failure for ASCE/SEI 7 loads (Stevens and Kesner 2016).

In the assessment of potentially dangerous structural conditions, the licensed design professional should determine if it may be appropriate to include: structural redundancies, alternate load paths, primary and secondary supporting elements, redistribution of loads, collapse mechanisms, reduced live loads, measured displacements (sagging, listing, leaning, and tilting), second-order effects, and other loads specific to the structure, such as drifting snow, lateral earth and fluid pressures, self-straining loads, ice, and floods. References for potentially dangerous structural conditions include: commentary to Chapter 1 of ASCE/SEI 7-10, Galambos et al. (1982), Ellingwood et al. (1982), and Ellingwood and Ang (1972). These references provide target reliability indexes, basic probability theory and concepts for an evaluation using the specific details of the demand as it
A.3.3 Assessment criteria for potentially hazardous structural conditions of concrete structures for seismic resistance, unless addressed by the authority having jurisdiction are limited to potentially hazardous conditions associated with Structural Performance Level, Collapse Prevention of structures in Seismic Design Category D, E, and F of ASCE/SEI 7 using Earthquake Hazard Level, BSE-1E and shall be determined using ASCE/SEI 41 and this Code. The design-basis criteria to address potentially hazardous seismic conditions in concrete structures shall be this Code and ASCE/SEI 41.

A.3.4 The design-basis criteria for structures without potentially dangerous conditions shall be determined in accordance with A.4 through A.9.

A.4—Substantial structural damage

A.4.1 Substantial structural damage shall be assessed using current building code demands. Substantial structural damage to vertical members of the lateral-force-resisting system shall be where in any story, the shear walls or columns of the lateral-force-resisting system are damaged such that the lateral-load-resisting nominal capacity of the structure \( \sum R_{cn} \) in any horizontal direction is reduced more than 33 percent from its predamage condition \( \sum R_n \). This relationship is given by Eq. (A.4.1a).

\[
\frac{\sum R_n}{\sum R_{cn}} \geq 1.5 \quad \text{(A.4.1a)}
\]

Substantial structural damage to vertical elements of the gravity-load-resisting system shall be where for any wall or column or group of vertical members of the gravity-load-resisting system whose tributary area is more than 30 percent of the total area of the structure’s floor(s) and roof(s) are damaged such that the total vertical nominal capacity \( \sum R_{cn} \) is reduced more than 20 percent from its predamage condition \( \sum R_n \) as defined by Eq. (A.4.1b) and concurrently where the current building code factored gravity (dead, live, and snow) load demand to in-place vertical design capacity ratio of the damaged members is more than 1.33, as shown in Eq. (A.4.1c). These relationships are given by Eq. (A.4.1b) and (A.4.1c).

\[
\frac{\sum R_n}{\sum R_{cn}} \geq 1.25 \quad \text{(A.4.1b)}
\]

\[
\frac{\sum U_c}{\sum \phi R_{cn}} \geq 1.33 \quad \text{(A.4.1c)}
\]

Capacities according to Chapter 6 and strength reduction factors per Section 5.3 or 5.4 shall be used in Eq. (A.4.1a) through (A.4.1c). The design-basis criteria shall be the current building code demands, supplemented by requirements of

RA.3.3 Compliance with ASCE/SEI 41 for Structural Performance Level, Collapse Prevention using an applicable Earthquake Hazard Level, BSE-1E should be reviewed and approved by the authority having jurisdiction for the assessment of potentially hazardous seismic conditions of concrete structures. Assessment of potentially hazardous seismic conditions for concrete structures is not required, but may be used, for structures in regions of low or moderate seismicity. If no requirements for potentially hazardous seismic structural conditions are provided by the authority having jurisdiction, the licensed design professional should reference ATC-78, the IEBC and ASCE/SEI 41 appendices for guidance.

RA.4—Substantial structural damage

RA.4.1 The assessment criteria for substantial structural damage are specific to existing concrete structures, which were adapted from the IEBC.

In Eq. (A.4.1c), the demand load is the current building code loads and load combinations and should include all current building code gravity loads judged to be applicable to the structure, such as drifting snow.

Supplemental requirements of this Code for the design-basis criteria include strength reduction factors per Section 5.3 or 5.4, capacities according to Chapter 6, repairs per Chapter 7, durability per Chapter 8, repair construction per Chapter 9, and quality assurance per Chapter 10 for existing structures. The referenced seismic design provisions of ASCE/SEI 41 are adapted from those defined in the IEBC.
RA.5—Conditions of deterioration, faulty construction, or damage less than substantial structural damage with strengthening

RA.5.1 Concrete structures with damage less than substantial structural damage, deterioration, or containing faulty construction have historically been restored to the strength of the original building code.

The demand/capacity ratio of limit of 1.0 as provided in this section allows strengthening repair that restores the structural reliability of the existing structure to the level prior to damage and deterioration.

Historical performance is often an acceptable indicator of adequate safety if the structure has been subjected to known loads even if the strength design demand or capacity of the structure based on the requirements of the original building code is significantly different from the current building code.

RA.5—Conditions of deterioration, faulty construction, or damage less than substantial structural damage with strengthening

A.4.2 The design-basis criteria for structures without substantial structural damage shall be determined in accordance with A.5 through A.9.

A.5—Conditions of deterioration, faulty construction, or damage less than substantial structural damage with strengthening

A.5.1 The demand/capacity ratio of the member, system, or structure of the work area shall be evaluated using the original building code demand ($U_0$) with nominal loads, load combinations, and capacities of the original building code to determine if the demand/capacity ratio exceeds 1.0, as shown in Eq. (A.5.1).

$$\frac{U_0}{\phi_o R_{cm}} > 1.0 \quad (A.5.1)$$

In Eq. (A.5.1a), $U_0$ is the strength design demand determined by using the nominal loads and factored load combinations of the original building code. $\phi_o R_{cm}$ is the capacity.
adjusted by the strength reduction factor (\(\phi_o\)) of the original building code.

If \(U_o/\phi_oR_{cn}\) is greater than 1.0, then strengthening repairs are required and shall be permitted to restore the structural capacity required by the original building code.

Repair of the existing concrete structure shall be permitted to restore a member, system, or structure of the work area to the capacity of the original building code based on the material properties of the original construction. New concrete members and connections to existing construction that are part of the repairs shall comply with provisions of A.2.4. If \(U_o/\phi_oR_{cn}\) is 1.0 or less, then strengthening repairs are not required.

If the demand/capacity ratio does not exceed 1.0, strengthening is not required.

A.5.2 Alternative assessment criteria shall be permitted, when approved by authority having jurisdiction using engineering principles for the member, system of structure of the work area of existing structures.

If the capacity of the structure is not in question, such as indicated by the commentary provisions of R1.7, assessment checks are not required.

RA.5.2 Assessment criterion other than the current building code or ASCE/SEI 41 may be used. The references of RA.3.2 should be considered in the selection of applicable assessment criterion.

Beyond using the current building code, the assessment criteria should address if the demand or capacity of the original structure or member is significantly inconsistent with current standards resulting in unacceptable structural safety. An increase in load intensity; added loads; changes in load factors, strength reduction factors, or load combinations; modification of analytical procedures; or changes in the determined capacity between the original and current building code (such as a change from allowable stress design [ASD] to strength design) should lead the licensed design professional to question the applicability of using the original building code for the assessment of an existing structure. Engineering principles used to determine acceptable structural safety are to use either a probabilistic evaluation of loads and capacities to show adequate structural reliability indices or an evaluation procedure using demand/capacity ratios that are derived from the basic engineering principles as presented in current standards.

An assessment criterion for a structure that has damage less than substantial structural damage, deterioration, or faulty construction that is based on the demand/capacity ratio threshold of 1.05 using the original building code or 1.1 using the current building code is:

(a) If the current building code demand (\(U_c\)) exceeds the original building code demand (\(U_o^*\)) increased by more than 5 percent (\(U_c > 1.05U_o^*\)), check the demand/capacity ratio using the current building code demand (\(U_c\)) to determine if it exceeds 1.1, as shown in Eq. (RA.5.2a).

\[
U_c/\phi_oR_{cn} > 1.1 \quad \text{(RA.5.2a)}
\]

If the demand/capacity ratio exceeds 1.1, then that system or member should be strengthened using the current building code demand. If the demand/capacity ratio does not exceed 1.1, then no strengthening is required.
(b) If the current building code demand ($U_c$) does not exceed the original building code demand ($U_{o*}$) by 5 percent ($U_c \leq 1.05U_{o*}$), check the demand/capacity ratio using the original building code demand ($U_{o*}$) to determine if it exceeds 1.05, as shown in Eq. (RA.5.2b).

$$U_{o*}/\phi R_{cn} > 1.05\quad (RA.5.2b)$$

If the demand/capacity ratio exceeds 1.05, then that system or member strength should be restored using the original building code demand ($U_{o*}$). If the demand/capacity ratio does not exceed 1.05, then strengthening is not required.

In this assessment criterion, the strength reduction factors ($\phi$) of Section 5.3 or 5.4 shall be applied in both Eq. (RA.5.2a) and (RA.5.2b).

The current building code strength design demand ($U_l$) combines current building code nominal gravity loads (dead, live, soil, and snow) and lateral loads from fluid, soil and wind (excluding seismic) using the factored load combinations of ASCE/SEI 7. The original building code strength design demand ($U_{o*}$) combines the original building code nominal gravity loads (dead, live, and snow) and lateral loads from fluid, soil and wind (excluding seismic) using the factored load combinations of ASCE/SEI 7.

It may be appropriate to consider detailing requirements for ductility when considering seismic resistance, redistribution of internal member forces, reduced live loads, measured displacements (listing, leaning, and tilting), second-order effects, and other loads specific to the structure, such as drifting snow, lateral earth and fluid pressures, self-straining loads, ice, and floods.

The use of structure-specific data is acceptable, if substantiated by the licensed design professional. For these assessment criteria, the demand/capacity ratio provisions of RA.5.2a may be used in the assessment, whether the current building code demand does or does not exceed the original building code demand increased by 5 percent.

A.5.3 If the concrete design criteria of the original building code used only allowable stress design, an alternate to using A.5.2 strength design criteria is to evaluate the demand/capacity ratio of the member, system, or structure of the work area based on allowable stress design load combinations and design service loads, and the demand/capacity ratio based on allowable stress design load combinations for demand ($U_l$) and resistance calculated using allowable stresses ($R_a$) as shown in Eq. (A.5.3)

$$U_l/R_a > 1.0\quad (A.5.3)$$

If the demand/capacity ratio exceeds 1.0, then strengthening repairs are required and shall be permitted to be restored to the structural capacity as required by the original building code. If the demand/capacity ratio is 1.0 or less, then strengthening shall not be required.

RA.5.3 Before 1963 and the “Building Code Requirements for Reinforced Concrete (ACI 318-63),” the design of reinforced concrete structures was based upon allowable stress or working stress design principles. Original building code demands should include nominal gravity loads (dead, live, and snow) and lateral wind forces or seismic forces using the load combinations of original building code. Consideration should be given to inclusion of measured displacements (sagging, listing, leaning, and tilting), second-order effects, and other loads specific to the work area of the structure, such as drifting snow, lateral earth pressures, self-straining loads, ice, and floods. Using allowable stress design is inconsistent with the reliability principles of strength design. To adequately address current safety levels, consideration should be given to verification using strength design provisions of A.5.2. It may be appropriate to consider detailing requirements for ductility when considering seismic resistance.
CODE

Repair of the existing concrete structure shall be permitted to restore a member or system of the work area to the capacity of the original building code based on the material properties of the original construction. New concrete members and connections to existing construction that are part of the repair shall comply with provisions of A.2.4.

A.5.4 Existing structures other than those to be strengthened per A.3 through A.5 shall use A.6 through A.9 to determine the design-basis code criteria.

A.6—Conditions of deterioration, faulty construction, or damage less than substantial structural damage without strengthening

A.6.1 If less-than-substantial structural damage is present, structures damaged, deteriorated, or containing faulty construction that do not require strengthening in accordance with A.5 shall use the provisions of Chapters 7 through 10 of this code as the design-basis code criteria.

A.7—Additions

A.7.1 Where additions are made that change the gravity load demands on the member, system, or structure of the work area of the existing structure, the demand shall be determined for the configuration prior to the addition using the original building code loads and load combinations and the configuration with the addition using the current building code loads and load combinations. For the existing elements of the work area required to support gravity loads of the addition where the gravity load demands of the current building code with the addition are more than the original building code without the addition increased by 5 percent, the design-basis code shall be the current building code, with this code for the existing member, system, or structure of the work area and the current building code for the addition.

For the member, system, or structure of the work area of the existing structure supporting gravity loads whose calculated capacity using this code is to be decreased as part of an addition, the elements of the work area shall be shown to have or be rehabilitated to have a demand/capacity ratio equal to or less than 1.0 for the current building code demand.

If the addition is not independent of the existing building for lateral-force resistance, the design-basis code criteria for the existing lateral-force-resisting system with the addition shall be the current building code for seismic assessment and design.

Exception: The licensed design professional shall be permitted to use the original building code load demands and capacities where the demand/capacity ratio for each lateral-force-resisting member, with the addition using the current building code, does not exceed the demand/capacity ratio without the addition using the original building code increased by 10 percent.

A.8—Alterations

A.8.1 Where alterations are made that change the gravity load demands on the member, system, or structure of the work area of the existing structure, the demand shall be determined

COMMENTARY

RA.6—Conditions of deterioration, faulty construction, or damage less than substantial structural damage without strengthening

RA.6.1 Serviceability requirements including deflection limits and reinforcement for cracking of the current building code are not requirements of this code, but should be considered in the assessment and repair of existing structures.

RA.7—Additions

RA.7.1 The exception permits the licensed design professional to use the original building code for the assessment and design-basis criteria of existing lateral-force-resisting members when the members of the existing lateral-force-resisting system comply with Eq. (RA.7.1).

RA.8—Alterations

RA.8.1 The exception permits the licensed design professional to use the original building code for the assessment and design-basis code criteria of existing lateral-force-
for the configuration prior to the alterations using the original building code loads and load combinations and the configuration with the alterations using the current building code loads and load combinations. For the existing elements of the work area required to support gravity loads of the addition where the gravity load demands of the current building code with the alterations are more than the original building code without the alterations increased by 5 percent, the design-basis code criteria shall be the current building code, with this code for the existing member, system, or structure of the work area and the current building code for the alterations.

When the capacity of the member, system, or structure of the work area of the existing structure supporting gravity loads is to be reduced as part of an alteration, the reduced capacity shall not be less than the current building code demand.

If the alteration increases design lateral loads, results in a structural irregularity per ASCE/SEI 7, or decreases the lateral capacity, the design-basis code criteria for elements of the work area shall be the current building code for seismic assessment and design.

**Exception:** The licensed design professional shall be permitted to use as an alternative the original building code load demands and capacities for any lateral-force-resisting member, system, or structure of the work area where the demand/capacity ratio with alterations using the current building code is not more than the demand/capacity ratio without alterations using the original building code increased by 10 percent.

**A.9—Change of occupancy**

**A.9.1** Where the use or occupancy change demand on the member, system, or structure of the work area of the existing structure, the demand shall be determined using the original building code loads and load combinations and using the current building code loads and load combinations. For the existing elements of the work area when demand based on the current building code is greater than the demand on those elements based on the original building code criteria, the affected elements shall be rehabilitated using the current building code demands and the capacities based on this code and the lateral-force-resisting system shall be evaluated and rehabilitated if necessary to meet the Basic Performance Objective for Existing Buildings, as defined in ASCE/SEI 41. New concrete members and connections to existing construction that are part of the rehabilitation shall comply with provisions of A.2.4.

For the configuration with the alterations using the current building code loads and load combinations and the configuration with the alterations using the current building code loads and load combinations. For the existing elements of the work area required to support gravity loads of the addition where the gravity load demands of the current building code with the alterations are more than the original building code without the alterations increased by 5 percent, the design-basis code criteria shall be the current building code, with this code for the existing member, system, or structure of the work area and the current building code for the alterations.

When the capacity of the member, system, or structure of the work area of the existing structure supporting gravity loads is to be reduced as part of an alteration, the reduced capacity shall not be less than the current building code demand.

If the alteration increases design lateral loads, results in a structural irregularity per ASCE/SEI 7, or decreases the lateral capacity, the design-basis code criteria for elements of the work area shall be the current building code for seismic assessment and design.

**Exception:** The licensed design professional shall be permitted to use as an alternative the original building code load demands and capacities for any lateral-force-resisting member, system, or structure of the work area where the demand/capacity ratio with alterations using the current building code is not more than the demand/capacity ratio without alterations using the original building code increased by 10 percent.

**A.9—Change of occupancy**

**A.9.1** Where the use or occupancy change demand on the member, system, or structure of the work area of the existing structure, the demand shall be determined using the original building code loads and load combinations and using the current building code loads and load combinations. For the existing elements of the work area when demand based on the current building code is greater than the demand on those elements based on the original building code criteria, the affected elements shall be rehabilitated using the current building code demands and the capacities based on this code and the lateral-force-resisting system shall be evaluated and rehabilitated if necessary to meet the Basic Performance Objective for Existing Buildings, as defined in ASCE/SEI 41. New concrete members and connections to existing construction that are part of the rehabilitation shall comply with provisions of A.2.4.
KEY CHANGES FROM ACI 562-16 TO ACI 562-19: SUMMARY OF REVISIONS

Modifications were largely based upon comments received informally after the publication of ACI 562-16.

Major revisions
The major changes are as follows:
(a) Text was added to simplify use of new materials that have the equivalent of an ICC-ES evaluation report in Chapter 1.
(b) The requirements for the basis of design report were simplified in Chapter 1.
(c) Clarified requirements related to detailing of existing reinforcing steel in Chapter
(d) The commentary in Chapter 8 was updated to include a listing of exposure categories that may affect durability.

Minor revisions
The minor revisions were aimed at improving the current text to improve readability and integration with other documents. An effort was also made for consistency in terminology with ASCE and other organizations.
As ACI begins its second century of advancing concrete knowledge, its original chartered purpose remains “to provide a comradeship in finding the best ways to do concrete work of all kinds and in spreading knowledge.” In keeping with this purpose, ACI supports the following activities:

- Technical committees that produce consensus reports, guides, specifications, and codes.
- Spring and fall conventions to facilitate the work of its committees.
- Educational seminars that disseminate reliable information on concrete.
- Certification programs for personnel employed within the concrete industry.
- Student programs such as scholarships, internships, and competitions.
- Sponsoring and co-sponsoring international conferences and symposia.
- Formal coordination with several international concrete related societies.

Benefits of membership include a subscription to Concrete International and to an ACI Journal. ACI members receive discounts of up to 40% on all ACI products and services, including documents, seminars and convention registration fees.

As a member of ACI, you join thousands of practitioners and professionals worldwide who share a commitment to maintain the highest industry standards for concrete technology, construction, and practices. In addition, ACI chapters provide opportunities for interaction of professionals and practitioners at a local level to discuss and share concrete knowledge and fellowship.

The American Concrete Institute (ACI) is a leading authority and resource worldwide for the development and distribution of consensus-based standards and technical resources, educational programs, and certifications for individuals and organizations involved in concrete design, construction, and materials, who share a commitment to pursuing the best use of concrete.

Individuals interested in the activities of ACI are encouraged to explore the ACI website for membership opportunities, committee activities, and a wide variety of concrete resources. As a volunteer member-driven organization, ACI invites partnerships and welcomes all concrete professionals who wish to be part of a respected, connected, social group that provides an opportunity for professional growth, networking and enjoyment.
